Vitamin E. To determine vitamin E status in cholestasis it is necessary to determine serum concentration of vitamin E (normal levels 5-20 μg/ml). In hyperlipidaemia, vitamin E is bound to lipoproteins; consequently the vitamin E / total lipid level ratio (normal adult level 0.8 tocopherol / g total lipids) reflects vitamin E levels better (11). Vitamin E deposits provide sufficient reserve for 1 – 2 years, with degenerative changes in the motor neurological system occurring only after 5 – 10 years of vitamin deficiency. Whilst progressive muscular degeneration in children with cholestasis is frequent, in adults neuropathy is unusual. Neurological changes affect primarily the posterior columns and are characterised by the absence of reflexes or loss of proprioception and ataxia. Correcting Vitamin E deficiency in children is achieved with α tocopherol, α tocopherol acetate or α tocopherol succinate. The initial dose 10 – 25 IU /Kg/day is increased progressively to 100 – 200 IU/Kg/day in order to obtain a normal vitamin E / total lipid ratio. Adults must be monitored for neurological signs. In moderate cholestasis parenteral vitamin E is administered: 200 mg IM twice per month or 400 mg PO once daily. Therapy continues for the duration of cholestasis, aiming to maintain a vitamin E / total lipid ratio of > 0.8 (47).

Vitamin K. Vitamin K deficiency occurs in severe cholestasis and leads to coagulopathies: spontaneous bleeding, severe hemorrhage in response to minimal trauma, etc.

The liver uses vitamin K in the synthesis of clotting factors: II, V, VII, VIII, X, XI, XII and XIII. Vitamin K status is determined through prothrombin time (PT), serum vitamin K levels and clotting factors II, VII, IX and X. Vitamin K deficit can pe corrected by oral administration of soluble vitamin K (2.5 – 5 mg twice weekly) which can be increased up to 5mg daily until the prothrombin time is corrected. Patients with severe hemorrhage must be treated with IV, IM or SC vitamin K: 10 mg/day for 2 – 3 days, then 10 mg IM monthly (48).

In conclusion, clinical manifestations of fat-soluble vitamin deficiencies occur only in advanced cholestatic disease. The degree of vitamin deficit is proportional to the severity and evolution of the disease. Vitamin levels must be assessed twice per year. Vitamin supplements are administered indefinitely only in symptomatic cases or if biochemical analysis reveals vitamin deficiencies (49).

STEATORRHEA

Bile salts are needed for the luminal absorption of fat-soluble vitamins. Steatorrhea is a normal manifestation of severe cholestatic conditions that evolve over long periods of time. It occurs as a result of changed absorption, solubilisation and lipolysis of triglycerides in the intestinal lumen, which can be associated with exocrine failure of the pancreas (especially in PBC), celiac disease and *sicca syndrome* (50). Therapeutic intervention include: decreased fat intake: 40 – 50g / day, intake of short chain triglycerides (which do not require bile salts for absorption), a reduction in the dose of cholestyramine, pancreatic enzymes, a gluten free diet in the presence of celiac disease.

CONCLUSIONS

Often ignored in clinical practice, the assessment of extra-hepatic complications in patients with hepatic cholestatic conditions allows a more efficient management of this patient group. Pruritus, fatigue and osteoporosis are often overshadowed by other manifestations of liver disease which dominate the clinical presentation. In the last decades, significant progress has been made in understanding the molecular path physiology of cholestasis, although not many findings can be clinically applied. In an age of research targeting nuclear receptors in cholestasis, the pathogenesis of pruritus and fatigue remains as yet uncertain. Furthermore, current guidelines recommend the same first line therapeutic interventions – cholestyramine and rifampicin – as were reported 20 years ago. New studies are needed to determine more effective methods of diagnosis, prophylaxis and therapy of the extra-hepatic manifestations of cholestasis, in order to improve the quality of life in this patient group.

CUTANEOUS MYIASIS CAUSED BY CORDYLOBIA ANTHROPOPHAGA. CASE REPORT (Abstract): Cutaneous myiasis due to infestation by the larva of *Cordylobia anthropophaga* (*C. anthropophaga*) is rarely seen in Europe. It is important to correctly identify such cases to prevent a delay in treatment in geographical regions where *C. anthropophaga* (tumbu fly) is endemic or in the case of patients who have travelled to these areas, because the clinical findings can be attributed to other furuncular lesions (such as furunculosis, cutaneous abscesses, tuberculosis, or mycosis). We report the case of a patient with furuncular myiasis due to the larvae of *C. anthropophaga* earlier misdiagnosed as furunculosis in a patient returning from tropical Africa (Senegal), part of the habitat of *C. anthropophaga*. The patient was treated in Luxembourg, Europe, country that does not belong to tumbu fly endemic areas. Our case was successfully resolved by minimally invasive surgery followed by antiseptic treatment. Antiparasitic medication was not required. **Keywords:** MYIASIS, CORDYLOBIA ANTHROPOPHAGA, CUTANEOUS FURUNCLE.

Cordylobia anthropophaga, also known as tumbu fly, putzi fly, tumba fly, mango fly, or skin maggot fly, is a species of *Calliphoridae* (blow-flies) with a habitat restricted to Central and East Africa. During the larval stage of development, it is a parasite of large mammals, sometimes affecting humans (1). The name anthropophaga stems from anthropophagos, "human eater" in Greek (2). Myiasis represents the infestation of a live host, large vertebrate mammals or humans, with maggots (larvae) belonging to flies of Order Diptera (two winged). The lesions appear predominantly on the skin but may affect even body orifices (nose, ears, eyes, genital area) or even intestines (3). A distinction can be made between post traumatic lesions (when the larvae are deposited in wounds) and furuncular lesions (4).

Similar lesions can be made by other parasites such as *Cordylobia rwandae* and *Cordylobia rodhaini*, (5) otherwise known as the Lund fly, an organism endemic to the tropical forests of Africa, and *Dermatobia hominis*, or the human botfly, which can only be found in Central and South America (8). However, the transmission of *Dermatobia hominis* differs significantly from that of *Cordylobia* species. *D. hominis* usually requires an intermediate vector, such a blood-sucking insect (ticks, mosquitoes).

Adult flies deposit their eggs onto the intermediate host (6). Once the host encounters a worm-blooded host larva begin to hatch and invade exposed skin areas of the limbs, trunk or head. Females from the *Cordylobia* species tend to deposit between 100 and 300 eggs directly in sandy soil, often contaminated with feces or onto dirty or wet clothing that has been let outside to dry (7). The hatched larvae can survive in the ground for about two weeks, afterwards requiring a host to continue developing (7) Movement of the contaminated soil determines the larvae to surface and attach to the skin. If a larva finds a host, it penetrates the skin and in 8 to 12 days it develops through the three larval stages before reaching the prepupal stage, after which it can leave the host to burry itself into the ground where it pupates, finally becoming an adult fly that is capable of reproduction to continue the life cycle again (7). Thus, the larvae tend to hatch and invade either covered skin areas that were in contact with clothes such as the genital area, buttocks, trunk or areas that were in contact with contaminated soil such as the soles of the feet (4).

CASE REPORT

A 33-year-old woman living in Luxembourg was referred to the surgery clinic of the Centre Hospitalier de Luxembourg by the Department of Infectious Diseases with a week-old history of several boils (furuncles) on the thighs. The patient was right-handed, smoked 12 cigarettes a day and occasionally consumed alcohol. She worked as a schoolteacher and was allergic to pollen. Her past medical history revealed malaria and surgical interventions, a left adnexectomy in 2016, tonsillectomy and adenoidectomy in her infancy. At the time of her consultation she was under treatment with Malarone, a drug combination of atovaquone/proguanil, an antimalarial medication used in both the treatment and prevention of malaria.

Her symptoms gradually increased in severity over the past week, with itching, inflammation and pain that motivated the patient to present herself to the emergency department of the hospital where a diagnosis of furunculosis was initially made. The patient was examined by our colleagues from the Department of Infectious Diseases and referred to the Plastic Surgery Department for surgical excision and drainage of the furuncles. Routine history taking revealed that she had recently returned from a trip to Dakar, Senegal, one of the countries where *Cordylobia anthropophaga* is endemic. The locals usually hang their clothes to dry outside in the sun and do not iron them. Upon examination several discharging orifices were identified on the dorsal aspect of both thighs, each surrounded by mild inflammation. Closer inspection revealed movement in the center of the sinuses (fig. 1).

Fig. 1. Furuncular lesion with sinus containing *Cordylobia anthropophaga* larva

We diagnosed five furuncular myiasis lesions on the dorsal aspect of the thighs. The larvae were easily removed using pressure and small forceps. One larva was dif-

ficult to extract from the affected area, requiring surgery. After injecting local anesthesia, we performed a small incision following the Langer lines of skin tension to facilitate forceps extraction followed by a careful debridement of the purulent content. The larvae were subsequently identified by the hospital pathologist as belonging to *Cordylobia anthropophaga*. The patient was placed on a 7-day course of amoxicillin trihydrate equivalent to 875 mg amoxicillin and potassium clavulanate equivalent to 125 mg of clavulanic acid t.i.d. and tetanus toxoid prophylaxis, analgesia and daily dressings with Chlorhexidine were prescribed. A routine follow-up one week later showed that all the lesions had healed, and the patient did not present any complications or recurrence.

Fig. 2. The extracted *Cordylobia anthropophaga* larva

DISCUSSION

Mammals such as dogs and small rodents can also be a reservoir for this parasite with occasional human infection (8). Many cases of myiasis affecting different human organs have been described since then (3, 9-11) In most cases the diagnosis can be made solely relying on the clinical findings. The patient either lives in an endemic area or has recently travelled to one. Clinically upon inspection we can find several non-healing cutaneous lesions, itching or movement under the skin, inflammation or pain, sometimes serous discharge or even a worm-like structure protruding from the central punctum (4). The clinical appearance can be attributed to other furuncular lesions such as cellulitis, furunculosis, cutaneous abscesses, tuberculosis, mycosis, actinomycosis, fungating carcinoma, tuberculosis and chronic ulcerating abscess (4). In most cases the diagnosis is confirmed by the extraction and examination of larvae morphology, however sequencing of the 28S rRNA gene can also be performed (12, 13). Radiological investigations such as ultrasonography and mammography may be helpful, having already been used in the identification of *Dermatobia hominis* by hyperechoic nodule representing the larvae surrounded by a hypoechoic halo corresponding to the cavity (14).

The therapeutic objective is to remove the larvae and prescribe a course of antibiotics. Very few *C. anthrophaga* infestations get complicated by secondary bacterial infection, in most cases the secretions from the larva tend to inhibit bacterial growth, a common property identified in several fly types (15). In most cases the larvae can be removed without incising the skin, by covering the punctum (also serving as the air supply for the maggot) with oils, Vaseline petroleum jelly or other ointments, even butter or liquid paraffin (8). The same effect can be obtained by using a clear film dressing such as Opsite or Tegaderm, causing the maggot to begin struggling for air, forcing it to come out of the skin (16). Another treatment suggested by Dybbro (17) is to inject a combination of anesthetic and epinephrine into the insect chamber to obtain the same suffocating effect. In some cases, the use of a forceps may be required, also after injecting local anesthesia, such as lidocaine, an incision can be made over the lesion to facilitate

extraction. Complete removal of the larva is essential, as any leftover fragments could cause an inflammatory response or a granuloma (10). This must be done carefully, and the entire larva extracted as any remnant may provoke an inflammatory response (15). Sometimes simply applying pressure to the sides of the furuncle is enough to mobilize the larva, *C. anthropophaga* having smaller hooked bristles on the cuticle than those of *Dermatobia hominis* (18).

Boggild (19) described a method for extraction of *D. hominis* larvae using a snake venom extractor However, snake venom extractors are not commonplace in European Emergency Departments, thus we propose a more affordable and accessible method. Using two Luer Lock type Syringes and a Luer Lock type Syringe Connector, we can create a vacuum chamber by removing the piston from one of the syringes and attaching it to the skin over the myiasis lesion, creating enough suction to pull out the larva, after careful expansion of the punctum using small forceps. Morselli (20) described this type of installation, used in fat grafting procedures for processing and producing the adipose cells. After removal the lesions tend to heal quickly. Rare complications have been cited in the literature such as cellulitis, abscess formation, osteomyelitis and tetanus (21).

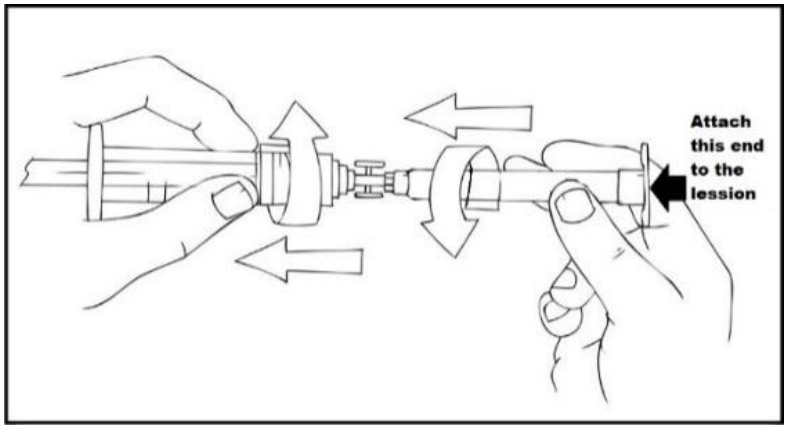

Fig. 3. Extraction method using a vacuum chamber created with the help of two syringes and a syringe connector. (Image adapted by the author from https://www.pfizer.de/medikamente-produkte/rezeptpflichtige-medikamente/pfizer-produkte/detailansicht/refacto-afR/)

CONCLUSIONS

Our paper presents the case of a European patient who had travelled to an endemic country and presented several furuncular lesions that had been initially misdiagnosed. Considering recent developments with an increasing number of people traveling to endemic countries or coming to European countries from these destinations, as well as the effects of climate change, cases of human myiasis could become even more frequent in countries in which it is rarely encountered. Although it remains a relatively uncommon condition in Europe, an increased awareness of its clinical aspects is more and more important to rapidly provide proper treatment.

3. Clinica a III-a Chirurgie

TREATMENT OF PERITONEAL CARCINOMATOSIS OF GASTRO-INTESTINAL ORIGIN - A RETROSPECTIVE STUDY ON 203 CASES (Abstract) Peritoneal carcinomatosis of gastrointestinal origin (PC-GI) is an advanced digestive tumor and is found in 10-30% of patients (P) with primary surgery for cancer (C) and up to 50% of C recurrences. **Aim**: to evaluate the main characteristics, ethio-pathogenesis, prognosis and imaging to track of P with PC-GI admitted to the Third Surgical Clinic, „St. Spiridon" Hospital, Iaşi. **Material and methods**: A retrospective study was carried out on series of 203 patients admitted in the period June 2006 - March 2011. The patients were aged between 27-80 years (average 62), with a women / men ratio of 95/108. The duration of hospitalization was between 1 and 61 days, with an average of 13.5 days for emergency cases and 15 days for elective cases. The data from observation files, the operating protocols, pathology reports and follow-up files were collected and analyzed. **Results**: 136 patients were hospitalized with synchronous PC (the most common gastric N = 60) and 67 with metachronous PC (the most common colon N = 29). Imaging investigations consisted of ultrasound and computer tomography that showed a sensibility and specificity of 80% and 73 % respectively, mainly in regard to ascites but less in assessing the presence of peritoneal deposits. The most common complication was septic shock and mortality was 9.5% (17 patients). Average survival was 5.7 months. **Conclusion**: PC-GI is a disease with a poor prognosis, posing difficulties in early diagnosis, establishing the surgical indication and protocol. Consistent advances in systemic and locoregional chemotherapy, surgical techniques, intraoperative radiotherapy, as well as immunotherapy are expected to improve prognosis. **Key words:** PERITONEAL CARCINOMATOSIS, CHEMOTHERAPY, PALLIATION, ASCITIS.

Carcinomatoza peritoneală cu punct de plecare digestiv (CP-D) a fost considerată mult timp o boală incurabilă. Incidența CP-D este dificil de apreciat. În 2002 (Global Cancer Statistics - 2002) dintr-un total de 1.023.152 pacienți cu cancer colorectal, 15% aveau carcinomatoză peritoneală (CP), din 933.937 pacienți cu cancer gastric, 40 % aveau CP, din 232.306 pacienți cu cancer pancreatic 25% aveau CP (1).

Diagnosticul şi stadializarea în CP-D sunt dificile: dozarea serică a markerilor tumorali, examenul ecografic şi examenul tomografic computerizat (CT) sunt metode

frecvent utilizate. Markerii tumorali au o specificitate şi o sensibilitate crescute atunci când sunt determinaţi în lichidul de ascită (2). Sensibilitatea examinării CT variază funcţie de dimensiuni: 9-24% pentru nodulii subcentimetrici şi până la 65% pentru cei de peste 5 cm (3). Studiile recente (4) recomandă FDG-PET ca fiind cea mai utilă explorare în CP.

În studiul EVOCAPE din 370 de pacienţi cu CP cu chimioterapie sistemică speranţa de viaţă a fost cuprinsă între 3 luni (noduli de CP peste 2 cm) şi 9 luni (noduli sub 5 mm).

Mai multe studii multicentrice comparative nerandomizate au evidenţiat beneficiul în ce priveşte supravieţuirea pacienţilor şi durata fără semne de boală la P la care administrarea chimioterapicului s-a efectuat intraperitoneal intraoperator şi apoi sistemic. În singurul studiu randomizat referitor la CP cu punct de plecare colorectal, Wervaal şi col.(5) au constatat o supravieţuire medie de 22 de luni în lotul de P la care s-a practicat chimioterapia intraperitoneală hipertermică asociată citoreducţiei peritoneale faţă de o supravieţuire medie de 12 luni la lotul de P la care la tratamentul chirurgical s-a asociat chimioterapia sistemică, diferenţa a fost una semnificativă statistic.

MATERIAL ŞI METODĂ

În perioada iunie 2006 - martie 2011 în Clinica a III - a Chirurgie au fost internaţi 203 pacienţi cu diagnosticul de CP-D stabilit prin intervenţie chirurgicală cu confirmare bioptică şi/sau descriere macroscopică a leziunilor peritoneale sau în baza unor explorări imagistice cu suspiciune ridicată pentru CP la pacienţii cu istoric de tumoră digestivă operată.

Din foile de observaţie, din protocoalele operatorii, buletinele anatomo-patologice, registrele de control, protocoalele oncologice şi din datele furnizate de Serviciul pentru Evidenţa Populaţiei au fost extrase principalele caracteristici clinico-epidemiologice, de diagnostic, tratament, evoluţie şi prognostic. Culegerea datelor şi statistica descriptivă a fost efectuată cu ajutorul programului *Microsoft Excel 2007*.

REZULTATE

Din analiza principalelor caracteristici clinico-epidemiologice ale P (tab. I) se observă o uşoară predominanţă a sexului masculin, o durată de spitalizare în medie egală între P cu CP sincronă (CP-S) şi CP metacronă (CP-M).

TABELUL I

Caracteristici clinico-epidemiologice ale pacienţilor cu carcinomatoză peritoneală internaţi în Clinica III Chirurgie în perioada iunie 2006-martie 2011

Pacienţi 203	Femei → 95
	Bărbaţi → 108
Vârsta 20-87 ani	Media → 62 (38-86)
Durata de spitalizare 1-61 zile	Media → 14 (1-27)
	Urgenţe → 13,5 (1-28)
	Electiv → 14,3 (3-27)
CP Sincronă 136	Electiv → 92
	Urgenţe → 44
	Ocluzii intestinale → 28
CP Metacronă 67	Electiv → 37
	Urgenţe → 30
	Ocluzii intestinale → 23

Cea mai frecventă cauză de CP-S a fost cancerul gastric (60 de cazuri – 44%) urmată de cancerul de colon; cea mai frecventă cauză de CP-M a fost cancerul de colon (29 cazuri – 39%) urmată de cancerul gastric (tab. II)

TABELUL II

Etiologia carcinomatozei peritoneale digestive la cei 203 pacienți

136 pacienți cu carcinomatoză sincronă				**67 pacienți cu carcinomatoză metacronă**		
Stomac	60			13		
Colon	31	cecoascendent	14	29	cecoascendent	10
		transvers	4		transvers	5
		transvers	13		transvers	14
Pancreas	19	cefaloistmic	5	7	cefaloistmic	5
		corporeocaudal	14		corporeocaudal	2
Rect	8			8		
Esofag	6			-		
Duoden	2			3		
Căi biliare	7			-		
Altele	7			7		

Au fost operați 109 pacienți cu CP-S (80%). În 25 cazuri (fig.1) s-au practicat rezecții cu viză paleativă, la 2 pacienții cu neoplasm colon drept cu CP s-a practicat hemicolectomie dreaptă cu peritonectomie parțială şi chimioterapie intraperitoneală normotermică pre- şi postoperatorie.

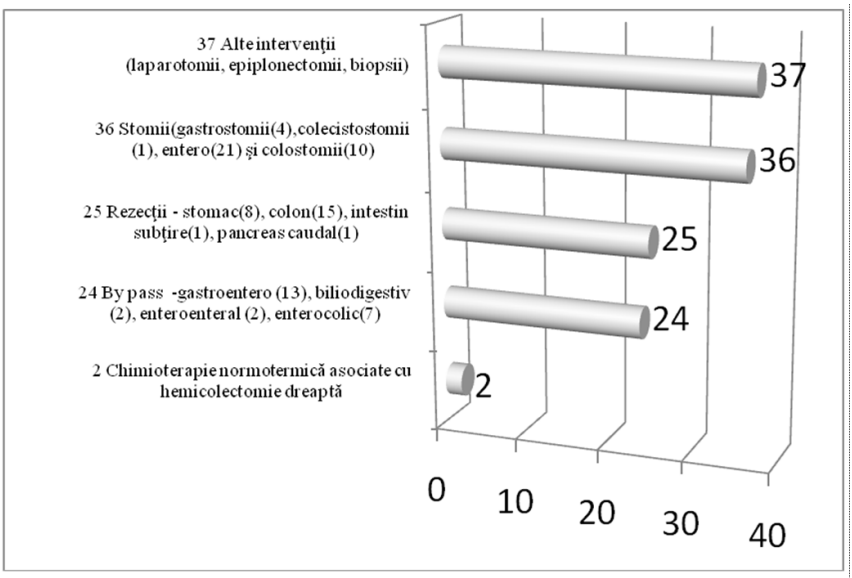

Fig. 1. Intervențiile efectuate în carcinomatoza peritoneală sincronă

Din 67 de pacienți cu CP metacronă au fost operați 53 de pacienți(79%); cele mai frecvente intervenții (fig.2.)au fost cele de *by-pass*. La 3 pacienți cu CP-M în antecedente cu cancere colon operate s-a practicat chimioterapie intraperitoneală pre- şi post-operatorie.

Examenul ecografic a fost a fost efectuat la 198 pacienți. 177 dintre aceştia au fost operați. Sensibilitatea şi specificitatea examinării ecografice în evidențierea ascitei a fost de 82% şi respectiv 71%.

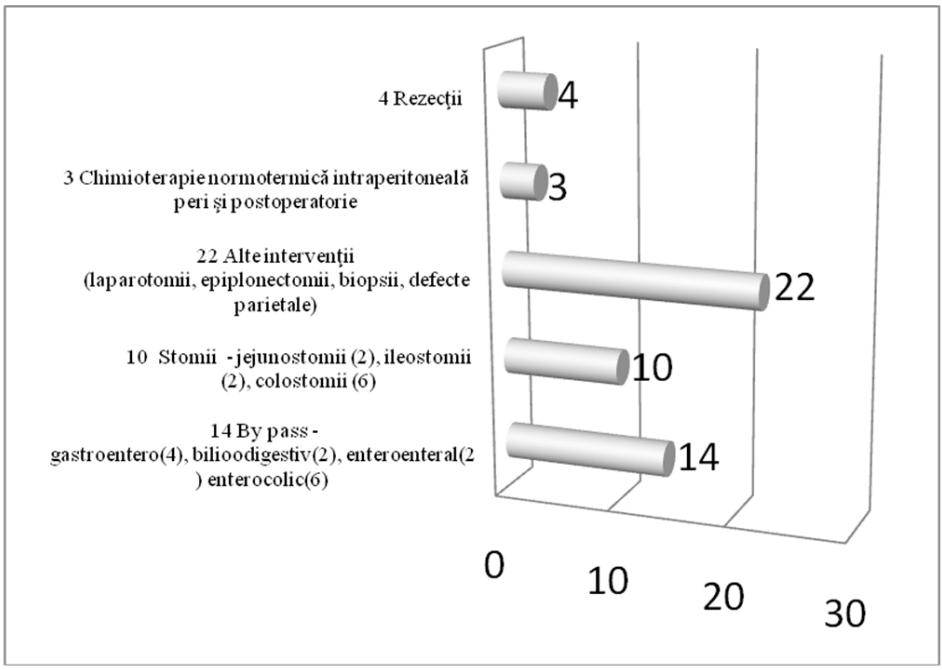

Fig. 2. Intervențiile efectuate în carcinomatoza peritoneală metacronă

Examinarea CT a fost efectuată la 40 din cei 203 pacienți (20%), aceasta s-a efectuat la 29 din 136 pacienți (21%) cu CP sincronă şi la 11 pacienți (16%) cu CP metacronă. În funcție de modul de prezentare a pacienților în 34 de cazuri (85%) examenul CT a fost efectuat la P electivi şi în 6 cazuri (15%) în urgență. Ascita a fost evidențiată la 12 P din cei operați şi care au efectuat şi examen CT, cu o sensibilitate şi o specificitate de 81% şi respectiv 78%. Îngroşări ale seroasei peritoneale au fost evidențiate la 23 P din care 17 au fost operați, sensibilitatea şi specificitatea au fost de 79% şi respectiv 73%).

Biopsia intraoperatorie asociată sau nu cu alte intervenții a fost efectuată la 131 pacienți din cei 179 operați (73%), a fost efectuată la 99 din cei 128 de pacienți cu CP sincronă (76%). În 29 de cazuri (24%) biopsia intraoperatorie nu a fost efectuată – 13 cazuri cu cancer gastric. La 32 din cei 51 de pacienți (62%) cu CP metacronă operați biopsia a fost efectuată.

Laparoscopia diagnostică a fost utilizată la 15 pacienți (7,5%). Laparoscopia a fost folosită la 12 pacienți (esofag-2, stomac-1, ficat-3, corp pancreas-5, necunoscute-2),

din cei 136 pacienți cu CP-S (9%) şi în 11 cazuri s-a prelevat şi biopsie. S-a efectuat ca singură intervenție laparoscopia diagnostică asociată cu biopsie şi la 3 cazuri de CP-M.

Din totalul de 136 de pacienți cu CP sincronă la 49 dintre aceştia s-a efectuat o sutură digestivă (25 rezecții, 24 operații de tip *by-pass*). Au fost 2 fistule (4%) digestive tratate conservator. Dintre cei 18 pacienți cu CP metacronă la care s-a practicat o sutură digestivă (4 rezecții, 14 operații *by-pass*) 2 P au dezvoltat postoperator fistulă digestivă, aceştia au decedat prin sepsis.

Mortalitatea postoperatorie la cei 177 pacienți operați a fost de 9,5% (17 decese postoperatorii). 15 P (88%) au fost operați în urgență iar 2 (12%) electiv. Principala cauză de deces a fost şocul septic - 8 pacienți (47%). Alte cauze de deces au fost hemoragia digestivă superioară cu soc hemoragic – 2 pacienți, insuficiența hepatorenală – un pacient, alte cauze – 6 pacienți.

Din 203 pacienți internați în Clinica III Chirurgie în perioada iunie 2006-martie 2011 la 1 martie 2011, 178 pacienți erau decedați. Supraviețuirea medie la pacienții cu CP de origine gastrică a fost de 4,2 luni. Supraviețuirea medie la pacienții cu CP de origine colorectală a fost de 6,5 luni. Un singur pacient diagnosticat în 2008 cu CP de la o tumoră de colon transvers metacronă (cu un neoplasm de colon drept operat în antecedente) la care s-a practicat totalizarea colectomiei şi apoi chimioterapie sistemică era în viața la 1 martie 2011. Supraviețuirea pacienții cu CP cu punct de plecare pancreas, ficat, căi biliare a fost sub 3 luni.

DISCUȚII

CP-D a fost considerată mult timp o afecțiune incurabilă iar tratamentul chirurgical propus unul paleativ. În prezent a crescut interesul tratamentul agresiv al CP cu scop creştere a duratei şi calității vieții şi chiar vindecare. Au fost definite noțiunile de citoreducție optimală şi suboptimală, stadializări în funcție de distribuția carcinomatozei scorul de completitudine al citoreducției. Deoarece tratamentul asociază mai multe manevre agresive (peritonectomii întinse, rezecții viscerale largi, hipertermia) intervențiile nu sunt lipsite de riscuri. Într-un studiu retrospectiv Sugarbaker şi col. (6) pe un lot de 356 pacienți operați pentru CP au constat o mortalitate intraspitalicească de 2%, complicații medii şi severe la 19 % din pacienți şi 11 % din pacienți au necesitat reintervenții chirurgicale.

Pe lângă morbiditatea şi o mortalitatea crescută un alt impediment în folosirea acesteia este prețul. Bonastre şi col.(7) pe un lot de 73 de pacienți operați între 2002-2003 în Institutul Gustave-Roussy au evidențiat un cost pe pacient de 39350 Euro cu o durată medie de spitalizare de 27 zile, în condițiile în care spitalului i-au fost rambursate o medie de 20500 Euro a rezultat un deficit de 1,4 milioane. Într-un alt studiu Deraco şi col.(8) pe un lot de 382 de pacienți pe în perioada 1995-2008 remarcă un cost pe pacient de 36.000 Euro cu o medie de spitalizare de 24,3 zile şi un deficit între valoarea valoare serviciilor şi valoarea rambursată de aproximativ 1.860.000 euro pe ultimii doi ani.

În prezent sunt în desfăşurare mai multe studii clinice de fază I/II cu noi clase chimioterapice iar rezultatele preliminare sunt încurajatoare. Catumaxomab este un anticorp trifuncțional recent introdus în tratamentul CP-D. Un studiu recent (9) pe un lot de pacienți cu CP-D tratați cu catumaxomab arată o supraviețuire medie de 502 zile cu absența evoluției la 11 pacienți

din 17.

În statistica Clinicii a III - a Chirurgie în perioada iunie 2006 - martie 2011 au fost tratați 203 pacienți. Cancerul gastric a reprezentat cauza cea mai frecventă de CP-S iar cancerul de colon cauza cea mai frecventă de CP-M. Datorită istoriei naturale mai mulți pacienți cu cancere de colon local avansate operate ajung în faza complicațiilor ocluzive ce necesită reintervenții chirurgicale.

Principala investigație imagistică la pacienții internați în clinică a fost examinarea ecografică. Examenul CT în ciuda faptului că are o sensibilitate şi o specificitate mai mare a fost efectuat doar la 40 pacienți din cei 203, fapt explicabil atât prin accesul mai greu la explorare cât si printr-un procent relativ ridicat de pacienți internați în urgență (31%).

În ceea ce privește intervențiile chirurgicale, acestea au fost în marea majoritate paleative, ablația tumorilor a reprezentat 20% din intervențiile practicate pentru CP-S. La 5 pacienți (2 cu CP-S pentru neoplasm colon drept şi 3 CP-M pentru neoplasm colon operat) s-a efectuat chimioterapie preoperatorie normotermică urmată de chimioterapie intraperitoneală postoperatorie pe o perioadă cuprinsă între 2 şi 4 zile. Administrarea chimioterapicului (CIS-PLATIN) intraoperator şi apoi postoperator nu a influențat evoluția postoperatorie imediată a pacienților, un singur pacient a prezentat insuficiență renala acută reversibilă. După externare pacienților li s-a administrat chimioterapie sistemică. Supraviețuirea pacienților a fost de 6,8 şi 9 luni, 2 pacienți au fost pierduți din evidență.

Rata relativ ridicată de complicații şi mortalitatea crescută (9,5%) sunt explicate prin numărul mare de pacienți internați cu complicații, de obicei ocluzive. Raportările centrelor cu experiență în tratamentul CP, o mortalitate de 0-6% după intervenții agresive (10-12) pot fi explicate şi prin faptul că aceste centre de obicei tratează pacienți atent selecționați şi care nu sunt urgențe chirurgicale.

CONCLUZII

Cu o incidență în creştere, o calitate a vieții afectată, supraviețuire scurtă, morbiditate şi mortalitate operatorie crescute, carcinomatoza peritoneală de etiologie digestivă rămâne o afecțiune dificil de tratat. În absența studiilor prospective multicentrice randomizate terapia acestei afecțiuni cu tablou clinic polimorf rămâne un subiect controversat si dificil de apreciat ca eficiență reală. Introducerea în arsenalul terapeutic a unor noi clase de chimioterapice, a unor intervenții chirurgicale agresive, şi eventual a terapiilor genice ar putea îmbunătăți prognosticul acestor pacienți.

MULȚUMIRI

Acest studiu a fost efectuat cu sprijinul unei burse doctorale in cadrul proiectului "Burse doctorale pentru doctoranzi competitivi în Aria Europeană a Cercetării" POSDRU/1.5/88/S/ID proiect 63117.

DIAGNOSTIC APPROACH OF PNEUMONIA IN AN ELDERLY PATIENT WITH CO MORBIDITIES - CASE REPORT

4th Medical and Geriatrics Clinic

DIAGNOSTIC APPROACH OF PNEUMONIA IN AN ELDERLY PATIENT WITH COMORBIDITIES **(**Abstract): Dyspnea is one of the symptoms that has a major impact on patients' health, with a negative influence on the quality of life. The main causes of dyspnea are cardiac, pulmonary and mixed (cardiac or pulmonary). There are several other causes such as metabolic conditions (acidosis), pain, neuromuscular disorders, otorhinolaryngeal disorders, anxiety, panic disorders and hyperventilation. Acute pneumonia in the elderly is a common occurrence and its incidence grows as the elderly population increases. We report the case of a 76 years old patient with a known cardiovascular condition, recently hospitalized for right pulmonary infarction. He presented to our clinic for influenced general state, rest dyspnea, fever, shiver, and productive cough in the last two days. Current medication included oral anticoagulants and triple antihypertensive treatment (responsible for his low blood pressure). Laboratory results showed a nonspecific inflammatory syndrome with leukocytosis and neutrophilia and mild normochromic normocytic anemia; D-dimers were within normal range, fibrin degradation products 1+; myocardial enzyme testing showed no alteration, and BPN (beta natriuretic peptide) was 790 pg/ml. Chest X-ray showed diffuse bilateral reticular shadows (more pronounced on the right side) and left costodiafragmatic opacification. It appears that age-related increase in morbidity and mortality in community-acquired pneumonia is not due to age per se, but to interactions between the immune system, systemic diseases and nutritional factors. Community-acquired pneumonia in the elderly is known to have a high mortality. Although the diagnosis can be easy, the physician must also investigate for less obvious causes of dyspnea such as the presence of comorbidities and fragility of the elderly patient. **Key words**: PNEUMONIA, ELDERLY, DYSPNEA.

Dyspnea is one of the symptoms that have a major impact on patients' health, with a negative influence on the quality of life. There are many causes of dyspnea in the elderly, most commonly cardiac (1) and pulmonary.

A list of causes of dyspnea should include: cardiac pathology (congestive heart failure, coronary artery disease, myocardial infarction, cardiomyopathy, valvular dysfunction, left ventricular hypertrophy, asymmetric septal hypertrophy, pericarditis, arrhythmias), pulmonary pathology (COPD, asthma, restrictive lung disorders, hereditary lung disorders, pneumothorax), mixed cardiac or pulmonary diseases (COPD with pulmonary hypertension and cor pulmonale, chronic pulmonary emboli, trauma), and

other causes (metabolic conditions such as acidosis, pain, neuromuscular disorders, otorhinolaryngeal disorders, anxiety, panic disorders, hyper-ventilation). Among the respiratory causes, pneumonia is of special importance due to its high frequency and its difficult management in the exponentially growing elderly population (2, 3). The diagnostic and therapeutic approach of this illness for patients aged over 65 requires extensive knowledge in the field of geriatric medicine because, on the one hand, it frequently presents with atypical symptoms and, on the other hand, because it often has a negative impact on the quality of life. It is also important to note that acute pneumonia in the elderly is a common occurrence and its incidence is growing as the elderly population increases (4).

Pneumonia is considered to be the sixth among the leading causes of death in the United States, with approximately 600.000 admissions per year (5, 6). Often, it can lead to serious complications and/or death.

The common symptoms of all viral pneumonias are fever, chills, nonproductive cough, rhinitis, myalgias, headaches, and fatigue. These symptoms are similar to those encountered in pneumonia, although studies have shown a lower probability of experiencing chest pain in viral pneumonia (7). Although most patients present with cough, in the elderly it may be only scant.

Viruses account for the largest proportion of childhood pneumonias. Viral pneumonia decreases in frequency in healthy young and middle-aged adults, but then increases substantially among the elderly. Studies on community-acquired pneumonias in patients over 65 years have consistently proved viruses to be the second most common etiologic cause (with the first one being *Streptococcus pneumoniae*), ranging from 13-50% of the diagnosed cases (7, 8, 9, 10).

CASE REPORT

We present the case of a 76 years old man with former tobacco and alcohol addiction, previously diagnosed with multiple cardiovascular co morbidities: high blood pressure (systolic pressure =230 mmHg), heart failure, atrial fibrillation, IIIrd degree heart block (treated with permanent VVI pacing), stage III peripheral ischemia (treated with thrombendarterectomy on left superficial femoral artery and left ilio-femoral by-pass), ischemic stroke in left carotid territory (that occurred 10 years ago and resulted in right hemiparesis). Two months before admission he underwent abdominal surgery (cholecystectomy); few days after the intervention he presented dyspnea; investigations revealed a right pulmonary infarction for which he received oral anticoagulation therapy at home.

His current reasons for admittance were rest dyspnea, productive cough with mucopurulent sputum, fever and shiver that had started 2 days before admission. Clinical examination showed an influenced general state and dyspnea with tachypnea; pulmonary auscultation revealed bronchial crackles on both pulmonary areas, and bilateral rales, more pronounced in the right hemithorax; his blood pressure was 85/60 mmHg under triple antihypertensive medication, heart rate 72/min. He also had presacral pressure sores 4/6 cm and right hemiparesis.

Laboratory analysis showed a nonspecific inflammatory syndrome with leukocytosis and neutrophilia - white cells = 16370/mm^3 (Normal value: 4000-9000/ mm^3), neutrophyles = 80% (Normal value: 55-70%), erythrocyte sedimentation rate = 34 mm/1h (Normal Value: 2-10 mm/1h) and mild normochromic normocytic anemia

(hemoglobin = 11.7 mg/dl and hematocrit = 36.2%).

D-dimer blood levels were within normal range, fibrin degradation products were 1+; myocardial necrosis enzymes were at normal value, BPN (beta natriuretic peptide) was 790 pg/ml (Normal value: <100), INR was 2,16 and oxygen saturation was 93% (Normal value: 95-100%) without the aid of oxygen mask.

Chest X-ray showed diffuse bilateral reticular shadows (more pronounced on the right side) and left costodiafragmatic opacification with an elongated lower left arc. Echocardiography revealed a mild dilatation of the left atrium (AS=41/51/58 mm), paradoxic movement of the interventricular septum and stage I mitral insufficiency; no vegetations were identified.

The Mini Mental State Examination (MMSE) showed mild cognitive dysfunction, with an average score of 24 (25 during the first examination and 23 the next day).

The patient was afebrile during his hospitalization, with preserved diuresis and heart rate between 70 and 76/min.

After a 10 - day therapy with broad spectrum antibiotics, i.v. corticotherapy and expectorant, symptoms decreased in intensity and dyspnea improved.

The dosage for antihypertensive medication was adjusted in order to obtain a good control of blood pressure and oral anticoagulant therapy was monitored according to INR values.

DISCUSSION

Although dyspnea in the elderly can be caused by both respiratory and cardiovascular diseases, the first diagnostic suppositions were pulmonary embolism and community-acquired pneumonia (CAP).

Dyspnea can be assessed by several tests and procedures in order to establish a definitive positive diagnosis. Those used on a regular basis are chest X-ray, spirometry, arterial blood gas measurement, EKG, exercise treadmill and echocardiography

Chest radiography is usually included among the first diagnostic tests. It can identify parenchymal or interstial lung abnormalities, opacities, nodules, etc. It can also evaluate the cardiac shape and size (relevant for conditions such as pericarditis and ventricular hypertrophy) and skeletal abnormalities relevant to the differential diagnosis.

Spirometry can help differentiate between obstructive lung disease (COPD, asthma) and restrictive lung disease (obesity, kyphosis or scoliosis, pleural effusion, neuromuscular disorders, systemic lupus erythematosus, sarcoidosis).

Arterial blood gas measurement can provide information about altered pH, hypercapnia, hypocapnia or hypoxemia. This measurement is more commonly used for the evaluation of acute dyspnea but it can also be used in the evaluation of chronic patients.

EKG can reveal arrhythmias, ischemia and/or other cardiac conditions that can cause dyspnea.

Exercise treadmill testing can identify ischemia as a cause of dyspnea. This test can be performed when symptoms are atypical for angina or when silent ischemia is suspected.

Echocardiography can detect a valvular abnormality and may be diagnostically helpful in patients with questionable murmurs in the context of dyspnea. It may also exclude sepsis and endocarditis (11) as possible dyspnea causes.

Pulmonary embolism and pneumonia are common complications that occur espe-

cially after stroke (12, 13, 14, 15), and due to the fact that they are clinically resemblant they can often be confounded. It is also true that the two pathologies can coexist, although many practitioners would rarely consider the possibility of pulmonary embolism if CAP is proved (16). These complications are frequently seen in the second to fourth week after stroke (16).

Among patients with symptomatic pulmonary embolism or deep venous thrombosis (DVT) that receive anticoagulant treatment for 3 months, fatal pulmonary embolism is rare during and following anticoagulant therapy. Patients presenting with pulmonary embolism are more likely to die of recurrent pulmonary embolism or DVT than patients presenting with DVT (17).

Riquelme et al.'s study underlined that the clinical picture of CAP in the elderly is often incomplete; they may have a large variety of signs and symptoms, with no association between them. Pleuritic chest pain was considered an independent risk factor for pneumonia caused by common microorganisms. Malnutrition was more common in patients with pneumonia than in patients without this pathology (18).

The quality of the diet in the aging population is influenced by physiological factors such as poor dentition, altered taste acuity, limited mobility, and polymedication. Elderly aged 74–80 years have less than 100 taste buds, whereas young adults have 250 (19). Psychological factors in this group that can contribute to poor oral intake include depression, dementia, and lack of motivation. Social factors that further compromise dietary intake include institutionalization, living alone, isolation during meals, and poor education. Similarly, in an aging population, economic factors such as reduced income, inadequate cooking, and health care costs can affect the quality of the diet (20).

In an elderly patient with pneumonia, the management plan is developed according to the clinical and instrumental assessment results. Compensatory strategies for increasing eating and swallowing efficiency and for reducing the risk of aspiration may involve modifying food and liquid consistencies and volumes. Dietary modification is a common management approach. Patients vary in their ability to swallow thin and thick liquids, semi-solids, and solids. The consistency of the patients' food should be individualized according to clinical testing findings. Dehydration in the elderly is one of the leading problems in nursing homes and long-term care facilities (21). Caution should therefore be taken with regard to the modification of fluids, as compliance with thickened liquids is often reduced. Small sips of cold water in patients with good oral hygiene may bring relief to thirsty patients and may reduce the resultant dehydration (22).

While the presence of dysphagia and the volume of the aspirate are key factors that predispose elderly patients to aspiration pneumonia, a number of other factors play an important role (23). Colonization of the oropharynx is an important step in the pathogenesis of aspiration pneumonia. The elderly have increased oropharyngeal colonization with pathogens such as *Staphylococcus aureus* and aerobic Gram-negative bacilli (*eg, Klebsiella pneumoniae* and *Escherichia coli*) (24, 25, 26).

Elderly patients with CAP represent a special group due to comorbidities, neurological impairment, and immunological and/or nutritional deficiency (18).

The incidence of fever in elderly with CAP is between 33% and 60% (4, 27).

Elderly patients with pneumonia commonly present with neurological symptoms. Delirium prevalence in hospitalized elderly with pneumonia varies from 50% (20), to values between 15% and 47% (4, 29).

In one study, chest radiography was compared to high resolution CT for the diagnosis of CAP (30). Chest radiographs detected an opacity in 18 of 47 patients (38.3%) suspected of having pneumonia, whereas high-resolution CT detected opacities in these 18 patients and in an additional 8 (55.3%) (30).

COPD, heart disease, malignancy, malnutrition, congestive heart failure, and diabetes mellitus have been implicated as risk factors leading to CAP in the elderly (18, 31, 32, 33, and 34).

It appears that age related morbidity and mortality in CAP is not due to age *per se* (29), but due to interactions between the immune system, systemic diseases and nutritional factors.

Mortality related to CAP is high. In his study, Riquelme showed that mortality was 26% (18) and it was in accordance with the results of other studies (4). Venkatesan and colab. reported that apyrexia is a prognostic indicator of mortality (4).

Optimal duration of antibiotic therapy for CAP has not yet been defined in prospective studies. Studies should be carried out to determine if a longer duration of therapy is necessary for elderly patients. Since about half the patients with CAP have respiratory symptoms at a 30-day follow-up, it is possible that longer therapy than that given at present may be beneficial. By convention, 10–14 days is the usual duration of therapy. Legionnaires disease should be treated for 21 days, as should pneumonia due to *Pneumocystis carinii* (31).

All elderly patients with CAP should undergo follow-up chest radiography to make sure that the pneumonia has resolved (31).

Optimum hospitalization in elderly with CAP is 15-16 days (4, 18).

Elderly patients who are functionally impaired (the frail elderly (35)) should be referred for geriatric assessment. Some of these patients may require admission to a geriatric rehabilitation center after the pneumonia has resolved. Studies have shown that geriatric assessment teams do improve the care of the elderly, resulting in a reduction in the number of patients who need discharge to long-term-care institutions (36). However, such assessment with only limited follow-up has not been effective (37).

Although the diagnose can be obvious, the differential diagnosis, clinical and paraclinical investigations must evaluate all etiological causes of dyspnea due to the presence of co morbidities and the fragile status of the patient.

NOUTĂȚI

EVALUAREA FUNCȚIEI RENALE REZIDUALE UTILIZÂND CYSTATINUL C

Su Jin Kim şi colaboratorii săi din Korea, au publicat un studiu important privind relaţia dintre funcţia renală reziduală (RRF) şi cystatinul la copiii cu dializă peritoneală (PD), atât la pacienţii anurici cât şi la cei cu RRF. Pornind de la faptul ca cystatinul C nu are corelaţie cu parametrii de baza pe care se evaluează eficienţa dializei, cum ar fi Kt/V pentru uree dar are o corelaţie semnificativă cu RRF, autorii conchid ca cystatinul C ar putea fi un bun indicator pentru RRF. Editorialul trece în revistă diferitele legături între cystatinul C şi uree, prezentate în literatura de specialitate privind adulţii, precum şi factorii determinanţi ai clearance – ului cystatinului C la pacienţii dializaţi. La adulţi, nivelurile cystatinului C sunt predominant determinate de RRF dar nu în exclusivitate. La hemodializa la pacienţi anefrici şi pacienţii cu PD există o corelaţie cu Kt/V săptămânal pentru uree. Nivelurile de cystatin C sunt, de asemenea, dependente de ultrafiltrare. În pofida acestor factori care influenţează cystatinul C după RRF, cystatinul C este un parametru util de monitorizare a pacienţilor cu PD care poate fi mai strâns corelat cu prognosticul pe termen lung decât o fac parametrii clasici de eficienţă ai dializei. (Filler G, Huang S-H S, Lindsay RM, Residual renal function assessment with cystatin C. *Ped Nephrol* 2011; 3(26): 333-335).

DRENAJUL ȚESUTULUI GRAS SUBCUTANAT LA GRAVIDELE OBEZE SUPUSE OPERAȚIEI CEZARIANĂ

Ana Maria Racă, R. Racă, O. Cărbunaru, M. Munteanu, N. Râcă
Spitalul Județean de Urgență, Craiova,
Clinica de Obstetrică - Ginecologie

SUBCUTANEOUS FAT TISSUE DRAINAGE IN OBESE PREGNANT WOMEN AFTER CAESAREAN SECTION (Abstract): The authors have analyzed the outcome of cesarean section celiotomy in obese pregnant women. The occurrence of postoperative wound infections, eventually dehiscence, in 2015 pregnant women who underwent caesarean section in a 3-year interval at the Craiova Ist Clinic of Obstetrics was studied. The analysis revealed the relation between postoperative wound infection and its topography, the type of fat tissue drainage (if done), and skin suture. The authors present a very effective method of subcutaneous drainage in obese pregnant women after cesarean section. **Key words:** OBESITY, DRAINAGE, INFECTION, CESAREAN SECTION

În ultimii ani se constată o creştere a procentului femeilor obeze în lume. In SUA aproximativ jumătate din populația feminină prezintă un grad de obezitate. În România procentul variază între 15-30%. Obezitatea creşte riscul de HTA, diabetului, infertilității, iar la gravide creşte prematuritatea, malformațiile congenitale, apare macrosomia fetală. În mod deosebit creşte riscul infecției puerperale (uter, anexe, cavitate buco-dentară, sâni, plagă postoperatorie).

În obstetrică plăgile în țesut gras se infectează cel mai frecvent. Infecția plăgii de celiotomie în țesut grăsos la femeile obeze este de 15 ori mai fracventă fată de femeile cu greutate normală.

În operațiile pe cale abdominală cavitatea peritoneală se deschide prin două feluri de incizii la peretele abdominal, respectiv incizie mediană şi incizie transversală (de obicei Pfannenstiel).

Alegerea inciziei depinde de cauza pentru care se intervine. De obicei incizia mediană se face în laparotomiile iterative, în abdomenul acut chirurgical, în urgențele mari obstetricale. Incizia transversală Pfannenstiel este preferată mai ales la femeile obeze. Avantajul inciziei mediene este că se execută rapid, permite orice fel de drenaj. Dezavantajul constă în faptul că expune la eventrații, la infecția plăgii, este mai puțin preferată din motive estetice. Incizia transversală Pfannenstiel este estetică, nu expune la eventrații şi infecția este mai rară.

Pentru a reduce o infecție locală este nevoie de o hemostază ingrijită, respectarea planurilor anatomice la sutură, evitarea spațiilor moarte, drenajul țesutului gras, asepsie riguroasă, material de sutură corespunzător. Majoritatea operațiilor obstetricale se fac prin incizie transversală suprapubiană. Cea mai frecventă este incizia

Pfannenstiel. Incizia la femeile obeze se execută în pliul de revărsare a şorțului gras abdominal, la 2-3 laturi de deget deasupra simfizei. Atenție la eventuala secționare a arterelor epigastrice la extremitatile secțiunii transversale. Închidrerea se face cu un eventual drenaj supraaponevrotic.

Mai există şi alte feluri de incizii transversale: incizia Rapin-Kusther în care se secționează tegumentele transversal şi țesutul subcutanat gras care se împinge spre ombilic, după care se deschide aponevroza şi peritoneul longitudinal; incizia Bordenheuer-Bastien în care incizia pielii se face de la o spină iliaca la cealaltă, la un lat de palma deasupra simfizei, se incizează transversal şi aponevroza cu fibrele muşchilor si peritoneul, la închidere capetele muschilor se suturează.

MATERIAL ŞI METODĂ

Definirea obezității în practică diferă de la autor la autor deoarece greutatea ideală este o noțiune abstractă. Astfel se consideră obez orice individ care depăşeşte cu 10-20% normele MTI (Metropolitan life insurance company statist. Bull 1959, 41 SUA). Noi am considerat obeze gravidele care au depăşit cu 15% normele MTI, dar am luat în calcul şi greutatea impusă de vârsta sarcinii – la termen 9-12 kg. Am exclus greutatea dată de patologia sarcinii sau altă patologie.

S-a urmărit pe o perioada de trei ani (2008-2010) prezența infectiei plăgilor abdominale şi eventual dehiscenței acestora în intervențiile chirurgicale obstetricale la garvidele obeze operate. Cu predilecție s-a urmărit infecția plăgii abdominale în relație cu topografia plăgii, cu drenajul supraaponevrotic, cu tratamentul instituit, cu germenii existenți în supurație.

Se descrie un procedeu, mai nou folosit în operațiile obstetricale, de drenaj al țesutului gras cu rezultate foarte bune.

REZULTATE ŞI DISCUȚII

Se constată o frecvență mare a infecției plăgii abdominale la femeile obeze, majoritatea cu incizie transversală. Pliul abdominal determinat de şorțul de țesut gras ce se revarsă este de fapt zona în care se face incizia transversală Pfannenstiel si zona unde există un grad mare de umezeală continuă şi greu aerisită.

Plăgile supurate au fost populate cel mai frecvent de germeni gram pozitiv (*Stafilococul Aureu şi Escherichia Coli*). Tratamentul a presupus în primul rând o toaletă riguroasă, administrare de spray cu aloe, sutura persecundum la nevoie, antibiotice, antiinflamatorii nespecifice.

Pentru a evita infecția țesutului gras în plăgile cu țesut gras intens reprezentat am procedat folosind un sistem de drenaj mai adecvat. Eficiența a fost foarte mare, nici o plagă neinfectandu-se.

Din 4704 de naşteri în Clinica I a Spitalului Județean Craiova 2015 (42%) au născut prin operație cezariană, din care 1800 (89%) prin incizie transversală Pfannenstiel. Din cele 2015 de operatii cezariană am contatat prezența obezitații la 350 (17,36%). Dintre acestea 7% au prezentat infecția plăgii care uneori a devenit dehiscentă. La nici un caz drenat supraaponevrotic prin metoda descrisă mai jos nu s-a produs infecția plăgii abdominale.

Descriem mai jos procedeul folosit:

Astfel am efectuat incizia transversal un pic mai sus de pliul şorțului de grăsime abdominal cu respectarea timpilor inciziei Pfannenstiel (fig. 1).

La deschiderea peretelui abdominal drenăm supraaponevrotic cu două tuburi de polietilenă scoase la comisurile plăgii, dacă

este posibil prin contraincizie. Tuburilor le adaptăm seringi la capetele exterioare cu care creăm vid (fig. 2).

Fig. 1. Drenajul țesutului grăsos în incizia Pfannenstiel

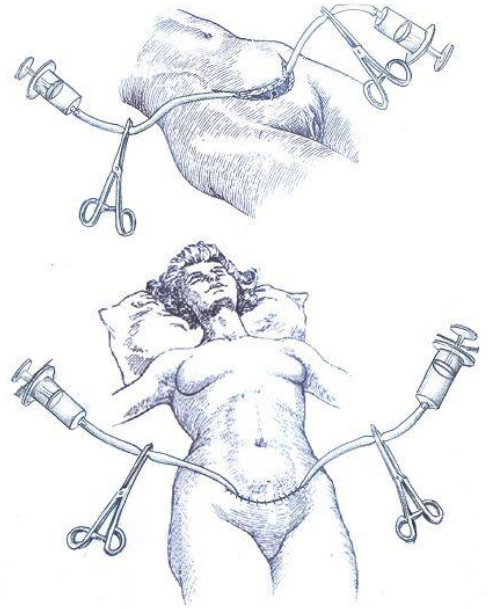

Fig. 2. Drenajul supraaponevrotic cu vid

Țesutul gras îl suturăm cu fire rare, iar tegumentul cu fire foarte dese. Prin aspirație cu seringa de o parte, apoi de cealaltă, creăm vid. Pensăm tubul, aruncăm conținutul seringii, apoi atașăm seringa, desfacem pensa, iar sucțiune, iar pensăm, aruncăm conținutul, atașăm seringa, desfacem pensa și așa mai departe pană eliminăm tot ce se absoarbe din plagă. La sfarșit atașăm seringa, desfacem pensa, tragem pistonul pentru a crea vid și îl fixăm cu un ac de seringă trecut transversal prin mânerul pistonului, pentru a se menține în pozitie de vid. Astfel secrețiile se adună în seringă și apoi procedăm din nou a doua zi la sucțiune. Drenajul durează 5-6 zile.

Procedeul este eficient și în inciziile mediene (fig. 3) și în suturile persecundum după plăgile dehiscente.

Fig. 3. Drenajul țesutului grăsos în incizia mediană

CONCLUZII

Infecția plăgii operatorii abdominale este mai frecventă la femeile obeze cu predominență la femeile gravide obeze.

Incizia Pfannenstiel făcută la nivelul plicii de revărsare a șorțului gras abdominal este des însotită de supurație datorită umezelii continue și spațiului neaerat.

Incizia transversală deasupra pliului este mai lipsită de risc supurativ.

Drenajul supraaponevrotic (după procedeul nostru) sub vid are o eficiență maximă, el poate fi aplicat şi în suturile persecundum.

CLINICOPATHOLOGICAL FEATURES OF JUVENILE GRANULOSA CELL TUMOR WITH AN EXTENSIVE MUCINOUS COMPONENT. CASE REPORT (Abstract): Granulosa cell tumors (GCTs) are a rare type of ovarian neoplasm accounting for only 2-3% and their mix with mucinous elements is uncommon. Despite their favorable natural course, correct diagnosis is imperative for proper management to prevent metastatic spread and local recurrences. We herein report a case of a 34-year-old female patient presenting to our clinic with a pelvic mass which required surgical removal. Her past medical history was peculiar: she was diagnosed with a right ovarian tumor for which she underwent total hysterectomy with bilateral salpingo-oophorectomy. Histological features of the specimen suggested the diagnosis of mucinous ovarian carcinoma. Seven years later, she underwent a right hemicolectomy for a tumor recurrence involving the ascending colon, followed by the same histological diagnosis. After another eight years, a computed tomography scan showed a pelvic tumor which was removed and after histological evaluation with extensive immunohistochemical staining the diagnosis was clarified: juvenile granulosa cell tumor with extensive mucinous component. Our case report emphasizes the necessity of immunohistochemical staining for accurate diagnosis, especially when clinical features do not correlate with histology findings. Moreover, due to the rarity of these types of tumors, further reports and studies are encouraged to standardize their diagnosis and treatment. **Keywords:** JUVENILE GRANULOSA CELL TUMOR; IMMUNOHISTOCHEMISTRY; OVARIAN CARCINOMA.

Granulosa Cell Tumors (GCTs) are a type of malignant sex cord-stromal tumors and account for only 2-3% of all ovarian neoplasms (1). They present as slow-growing masses with an indolent natural course. Two types of GCTs are described based on their histologic appearance: adult and juvenile GCTs. Adult type is the most common occurring in perimenopausal women, while juvenile GCTs are rare, accounting for roughly 5%, and arise in young females (2). Imaging findings vary

from well-defined solid masses with internal cysts to pure cystic lesions (3). Macroscopically they appear as encapsulated lesions with a smooth surface resembling cystadenoma. The classic microscopic features found in GCTs are Call-Exner bodies which are amorphous, eosinophilic, fluid-filled spaces formed by secretions from neighboring granulosa cells; however, Call-Exner bodies are found only in the adult-type GCT thus their absence cannot exclude a juvenile GCT. Immunohistochemistry (IHC) is the only tool to provide a specific diagnosis. Inhibin, calretinin, FOXL2 and SF-1 are specific positive markers, while epithelial markers such as CK7, EMA are negative markers (4, 5). Due to their rarity and favorable prognosis, standard treatment protocols are yet to be implemented. However, current management is multimodal. Surgery is the first step. Stage I tumors are candidates for fertility-sparing surgery, while advanced stages require total hysterectomy with bilateral salpingo-oophorectomy and, if needed, cytoreductive procedures. Adjuvant therapy consists of chemotherapy, radiation therapy and hormone therapy. Follow-up regimens are hardly adopted, however GCTs are prone to late recurrence therefore, imaging follow-up is needed to early depict tumor relapse (6, 7). Our aim is to present the clinical course of a rare recurrent GCT with mucinous infiltration initially misdiagnosed as mucinous ovarian carcinoma. GCTs can present in many different facets and have a tendency to behave unpredictably with late relapses demanding a high degree of expertise for accurate clinical and pathological diagnosis. Our target is to include this entity in the differential diagnosis of ovarian masses, to support immunohistochemical staining in inconclusive cases and by reporting them, prospective studies may be conducted to standardize GCT diagnosis, optimal treatment and follow-up, considering their recurrence rate.

CASE REPORT

A 34-year-old female patient was admitted to our clinic after being diagnosed on a follow-up computed tomography (CT) scan with a pelvic tumor. Physical examination revealed an abdominal mass in the hypogastrium, painful on palpation. The abdomen showed signs of collateral venous circulation, while lower extremities showed signs of bilateral deep vein thrombosis (DVT). Laboratory results were insignificant except for an iron-deficiency anemia and slightly elevated CA125 (37.8 U/mL).

In her past medical history, we found some prominent features. She was diagnosed with mucinous ovarian carcinoma, based on the immunohistochemical findings (tab. I), for which she underwent total abdominal hysterectomy with bilateral salpingo-oophorectomy. Despite the confirmed results, the patient refused chemotherapy.

TABLE I

Immunohistochemical analysis of specimen suggestive for mucinous ovarian carcinoma

Marker	CK7	ER	CEA	S100	Vimentin	CK20	P53	PCNA
Result	Focally +	60% +	-	-	+	-	-	30%

Seven years later the patient was diagnosed with a tumor recurrence involving the ascending colon. A right colectomy was performed as the tumor was adherent

to the cecum. Specimen analysis revealed the diagnosis of mucinous ovarian carcinoma. Noteworthy is that IHC was not performed. The patient received six cycles of chemotherapy with carboplatin and paclitaxel.

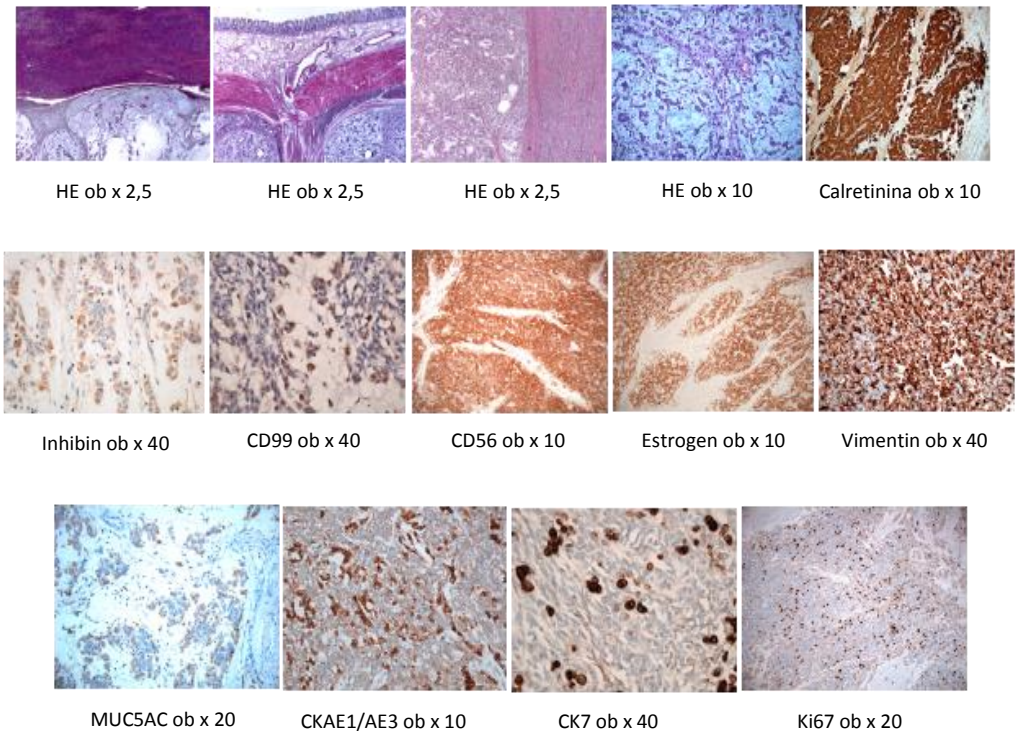

Fig. 1. IHC panel. Hematoxylin Eosin (HE) staining can be observed in the first four images. The next ten images show the presence of different IHC markers

Eight years later she was diagnosed in our clinic with an abdominopelvic tumor, the CT scan revealing a well-defined interhepatorenal tumor measuring 162/143/160 mm with direct invasion of the liver segment 6, right kidney, adrenal gland, and right diaphragmatic pillar. The mass had a compressive effect on the psoas muscle, caudate lobe, hepatic hilum, gallbladder and inferior vena cava (fig.1). Beside this mass, two other tumors were identified with the same features. One at the mesenteric root measuring 89/127/90 mm and another in the left pelvic area in direct contact with the sigmoid colon and bladder. In addition, multiple enlarged lymph nodes suggestive of metastatic spread were found in the paraaortic and external iliac regions, obturator fossa and mesentery. Intraoperatively, three tumors were identified. One measuring 120/15 mm located on the greater omentum, another measuring 80/100 mm attached to the mezosigmoid, and an infiltrative multilobulated mass in the right iliac fossa extending to the right upper quadrant and retroperitoneum. The masses were

removed along with the resection of the greater omentum, marginal hepatectomy, partial diaphragmatic peritonectomy, right nephrectomy and adrenalectomy, sigmoid colectomy and aortocaval lymph node dissection.

On receipt of the specimens, multiloculated, encapsulated masses were found. Cut section of the lesions showed a grey to white appearance with areas of hemorrhage, large cystic degeneration and mucinous content. Histopathological examination revealed round and fusiform cells with rich eosinophilic cytoplasm arranged in a lax architecture surrounded by mucus and rare Call-Exner bodies. Mitotic figures were 10/10 high power field. IHC testing was conducted and based on the expanded panel of markers (tab. II) the diagnosis was clarified: juvenile granulosa cell tumor with extensive mucinous component. Postoperative chemotherapy was initiated as soon as possible with cisplatin and etoposide.

TABLE II

IHC panel for the retrieved specimens

Marker	Result
CD 10	negative
EMA	negative
WT1	negative
CDx2	negative
CK20	negative
Podoplanin	negative
Inhibin A	focal positive
Calretinin	diffuse positive
ER	intense positive
CD 99	focal positive
CD 56	positive
MUC 2 and MUC 5 AC	low positive
Vimentin	positive
Cytokeratin AE1/AE3	positive and negative alternation
CK 7	focal positive
Ki 67	18% positive

DISCUSSION

Firstly, described by Rokitansky in 1885 (8), GCTs are sex cord tumors which can originate not only from granulosa cells, but also from interstitial cells, fibroblasts or techa cells explaining their occurrence in men. Morphologically, they are divided into two groups: adult GCT and juvenile GCT. This classification is based on their histological features, not on their epidemiology, thus adult GCT is indeed more frequent in postmenopausal women, but not exclusively. Adult granulosa cells show a solid organoid-like architectural pattern, with frequent pathognomonic Call-Exner bodies. In contrast, juvenile granulosa cells organize in nodular patterns, have a high mitotic index (and a worse prognostic), wide cytoplasm and rare Call-Exner bodies. Both types are usually unilateral, and both can differentiate into hormone-producing tumors. Juvenile GCTs are more frequent in younger patients, 90% of them being diagnosed at less than 30 years of age (3, 4, 5, 9, 10, 11).

Typically, GCTs present as slow-growing masses with a low malignant potential and favorable prognosis in comparison to epithelial ovarian cancers; however, they are at risk of early and late local recurrence, so a follow-up scheme is recommended including CT scans and tumor marker determinations. In these tumors the prognostic value of CA-125 is poor. Serum inhibin determination is a good choice for monitoring GCTs. Surgical removal followed by chemotherapy in recurrent cases is the mainstay of treatment. Radiation therapy has limited efficacy and hormone therapy is an option for hormone-producing tumors (12, 13, 14). Long-term follow-up including pelvic and abdominal examination, CT scan and tumor marker determina-

tion is recommended as delayed recurrences are characteristic for this disease.

Our case had a clinical presentation as a mucinous ovarian tumor with late relapses which required a high degree of suspicion for pathological diagnosis. We emphasize the importance of a complete immunohistochemical panel in differentiating ovarian masses. GCT cells usually stain positive for inhibin, calretinin, CD99, CD56, vimentin, estrogen and progesterone receptors. They are negative for CK7 and epithelial membrane antigen (EMA). After the first surgical excision of the ovarian tumor, the condition was mistaken for mucinous ovarian carcinoma. This confusion was possible precisely because the whole immunohistochemistry panel was not performed, in our case missing the determinations of inhibin, calretinin, CD 99, CD 56 and EMA. Next, after the removal of the right iliac fossa mass, immunohistochemical staining was not performed, supported by the previous histological exam, and a chemotherapy regimen for mucinous ovarian carcinoma was initiated. The recurrences were diagnosed each time in a locally advanced stage with adjacent visceral invasion because a follow-up sequence was not maintained since the patient did not stick to monitoring. Once the panel of immunohistochemistry markers is accomplished, a correct diagnosis can be made. The direct implications are connected to the appropriate adjuvant therapy and the necessity to track it in the long term. All these highlight the importance of identifying the whole immunohistochemistry panel in the case of patients with ovarian neoplasm, especially in the case of the young patients and when the tumor relapses over long periods of time.

CONCLUSIONS

We here presented a rare case of juvenile granulosa cell tumor misdiagnosed as mucinous ovarian carcinoma, emphasizing the necessity of performing a complete panel of immunochemistry markers. The rarity of these tumors as well as the lack of guidelines for the diagnosis and monitoring requires more insight into studying this disease.

FOLIC ACID AND RISK OF POSTPARTUM DEPRESSION

Postpartum depression, as a common complication of childbearing, is defined as an obvious depressive symptom or a typical depressive episode within 1 to 12 months after delivery. A cohort study aimed to assess the association between duration of folic acid supplementation during pregnancy and the onset of PPD in Chinese women. A total of 1592 participants were recruited, and data collected between July 2015 and March 2017 in Tianjin, China. Participants' baseline data were collected regarding socio-demographic and lifestyle characteristics, obstetric history, and folic acid supplementation during pregnancy. The Self-Rating Depression Scale, Chinese version was used to assess depressive symptoms at 6-12 weeks postpartum, and the prevalence of PPD in participants was 29.4%. Pregnant women who took folic acid supplements for more than 6 months had to lower prevalence of PPD, compared to those who took folic acid for less than 6 months. (Jing Yang, Yuyan Liu, Lujia Cao, Yuzhi Zheng, Wen Li and Guowei Huang. Association between Duration of Folic Acid Supplementation during Pregnancy and Risk of Postpartum Depression. *Nutrients* 2017; 9: 1206)

CLINICAL EPIDEMIOLOGICAL ASSESSMENTS ON 3521 PATIENTS SUFFERING FROM ROAD TRAFFIC INJURIES, IN RELATION WITH TRAUMA LOCALISATION AND SEVERITY, ASSISTED IN "SF. IOAN" EMERGENCY UNIT, DURING 2002 - 2009 (Abstract): **The aim** of study was to assess road traffic injuries in relation with their localisation and severity. **Material and methods**: A sample of 3521 patients suffering from road traffic injuries and assisted in "Sf. Ioan" Emergency Unit, Iaşi, Romania was assess regarding age group, sex and residence area, type of lesions and ther localisation and severity, between 2002-2009. Data were collected using a special epidemiological inquiry and processed using SPSS and MS Excel statistical softs. **Results**: The incidence of road traffic injuries increased during the last decade, with a report men/women of 1.5, urban and 21-30 age group predominance. The most frequent were leg fractures (16.7%) and thoracal contusions (19.1%), cranial and facial trauma (32.4%), with open injuries (10.5%). **Conclusions**: Prevention programmes with a high efficiency at the national level, as well as a concret identification of risk factors with a multidisciplinar approach of road traffic accidents, are needed. **Key words**: ROAD TRAFFIC INJURY, INCIDENCE, FRACTURE, CONTUSION

Accidentele de trafic rutier reprezintă o problemă majoră de sănătate publică, care afectează toate sectoarele societăţii. În anul 2009, datele statistice arată că 1.260.000 de oameni au decedat în accidente de trafic rutier, reprezentând 2,2% din totalitatea deceselor şi 25% din decesele provocate de accidente în general (cauza principală a deceselor pentru persoanele cu vârsta între 15 şi 44 ani şi pe locul 9 pentru toate categoriile de vârstă) (1,2,3,4).

Prognoza OMS pentru 2020 indică trecerea accidentelor de trafic rutier, de pe locul 9, pe locul 3 la cauza deceselor, după sinucideri şi afecţiuni cardiovasculare (şi acestea din urmă provocate de stres, sărăcie şi suprasolicitare) (2,5,6,7). Faptul că 90% din accidentele de trafic rutier, la nivel mondial, au loc în ţările sărace şi mediu dezvoltate şi numai 10% în ţările dezvoltate (care au reuşit să reducă consecinţele accidentelor de circulaţie cu 50% în ultimul deceniu), indică necesitatea unei mai mari implicaţii în realizarea unor programe de prevenţie, cu eficienţă sporită şi aplicabilitate la nivel comunitar (8,9,10,11,12).

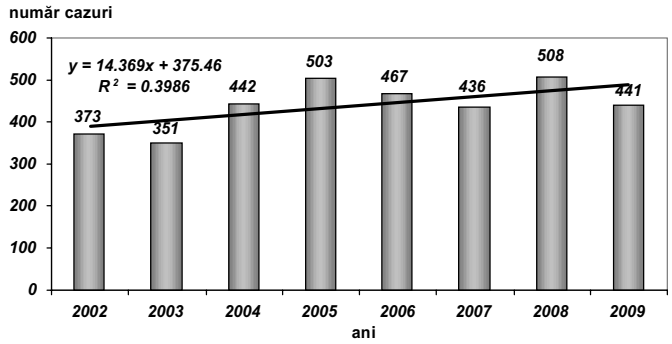

Fig. 1. Repartiţia numărului de cazuri de accidente de trafic rutier, pe ani, în judeţul Iaşi, în perioada 2002 - 2009

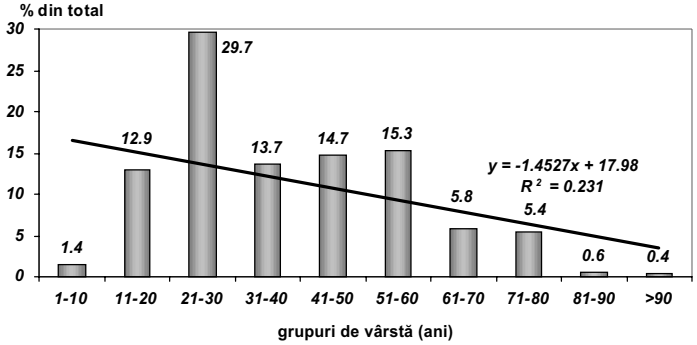

Fig. 2. Repartiţia numărului de cazuri de accidente de trafic rutier, pe grupuri de vârstă

MATERIAL ŞI METODE

Studiul a fost efectuat pe un lot de 3521 pacienţi, internaţi în secţia U.P.U. a Spitalului de Urgenţe „Sf. Ioan" Iaşi, în perioada 2002-2009. Culegerea datelor a fost realizată retroprospectiv, utilizându-se registrele de internare şi externare ale spitalului şi foile de observaţie ale pacienţilor. Prelucrarea datelor s-a efectuat cu ajutorul programului de statistică S.P.S.S. şi programului MS EXCEL 2007.

REZULTATE ŞI DISCUŢII

1. Incidenţa cazurilor de accidente de trafic rutier, pe ani, în judeţul Iaşi în perioada 2002-2009, arată o tendinţă crescătoare a numărului de cazuri, deşi în ani precum 2003, 2007 şi 2009 au fost înregistrate mai puţine cazuri, comparativ cu ceilalţi ani (2003 – 351 cazuri; 2007 – 436; 2009 - 441). Cele mai multe cazuri de accidente de trafic rutier au fost semnalate în anul 2008 (508 cazuri) (fig. 1).

Această tendinţă crescătoare a numărului de cazuri de accidente de trafic rutier poate fi pusă pe seama creşterii, mai ales în ultimii ani, a numărului de autovehicule, în situaţia în care condiţiile de carosabil au rămas aceleaşi sau chiar s-au deteriorat, aspecte observate şi de alţi autori (5,6,8,10).

2. Repartiţia pe sex şi medii a cazurilor de accidente de trafic rutier, în judeţul Iaşi, în intervalul de timp studiat, arată că sexul masculin a fost mai frecvent implicat (60,2%), faţă de feminin (39,8%), cu un raport bărbaţi / femei de aproximativ 1,5. Acest fapt are două posibile explicaţii: prima, ţinând cont de faptul că numărul de conducători auto de sex masculin este mai mare şi, deci, riscul este mai crescut; a doua explicaţie, de ordin psihologic, femeile conduc mai

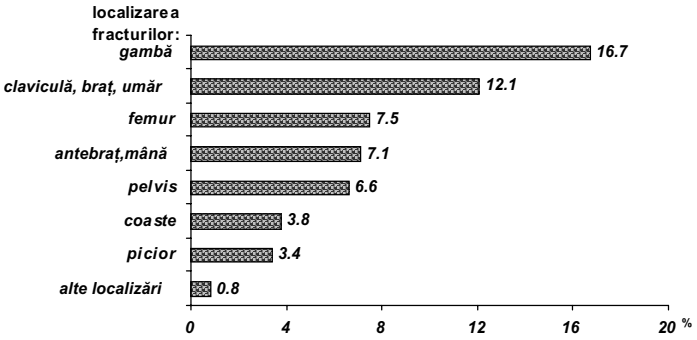

Fig. 3. Distribuţia fracturilor în funcţie de localizare

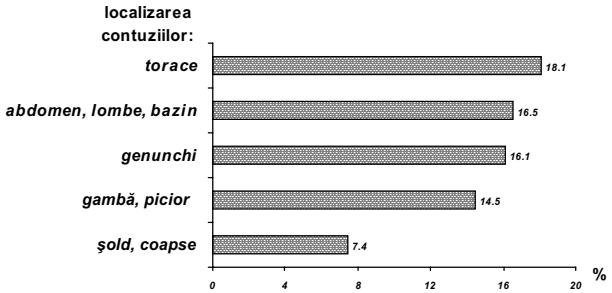

Fig. 4. Distribuţia contuziilor în funcţie de localizare

prudent, evită viteza excesivă, acordă o atenţie mai mare la semnele şi restricţiile de circulaţie. Repartiţia pe medii de reşedinţă a fost în favoarea celui urban, cu diferenţe statistic semnificative, în evaluarea cumulativă, pentru întreaga perioadă, cu explicaţia că în mediul urban, traficul este mai aglomerat, atât pietonal, cât şi pe carosabil.

Şi alte lucrări, publicate în ţară şi străinătate, evidenţiază faptul cert că bărbaţii sunt mai adesea implicaţi în accidente de trafic rutier decât femeile, cele mai multe accidente având loc în urban (2,4,6,9).

3. Repartiţia pe grupuri de vârstă a cazurilor de accidente de trafic rutier, luate în studiu, a înregistrat, pentru fiecare an, cât şi pentru întreaga perioadă, valori semnificativ mai crescute pentru grupul de vârstă 21 – 30 de ani (29,7% din total cazuri), urmat de 51-60 ani (15,3%) şi 41-50 ani (14,7%) (fig. 2). Această distribuţie a cazurilor poate fi explicată prin faptul că tinerii sunt mai frecvent implicaţi în trafic, atât ca pietoni, cât şi în conducerea autovehiculelor, în cadrul unor situaţii profesionale, familiale, relaţionale.

Date similare au fost menţionate şi în alte cercetări efectuate în diferite regiuni ale globului, atât în ţările dezvoltate, cât şi în cele cu un nivel socio-economic mai scăzut (3,5,10,11,12).

4. Repartiţia cazurilor de accidente de trafic rutier în funcţie de gravitatea leziuni arată faptul că procentul persoanelor care au suferit plăgi deschise a fost de 10,5%, comparativ cu plăgile închise, în procent de 89,5%. Numărul cazurilor de plăgi deschise, deşi mic, în comparaţie cu plăgile închise, este totuşi de luat în consideraţie, dată fiind gravitatea, de multe ori, extremă, a acestor leziuni, însoţite adesea de şoc hemoragic, comă, fiind responsabile de decesul rapid al acestor pacienţi accidentaţi în traficul rutier, înainte de a ajunge ambulanţa, aşa cum este precizat şi în lucrările altor

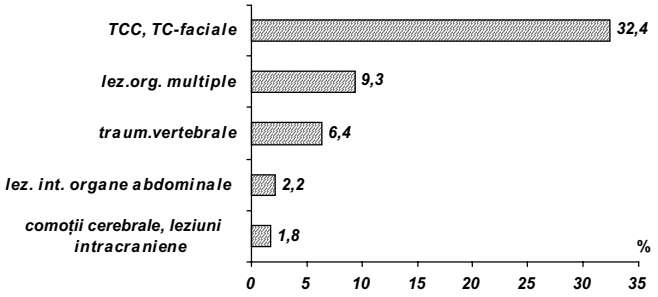

Fig. 5. Distribuţia leziunilor în funcţie de gravitate

cercetători (7,8,9).

5. Repartiţia fracturilor şi contuziilor în funcţie de localizare a arătat faptul că cele mai frecvente *fracturi* s-au situat la nivelul gambei (16,7%), urmate de localizarea la nivelul membrului superior (claviculă, braţ, umăr – 12,1%) (fig. 3). Comparativ, la nivelul toracelui s-au înregistrat cele mai multe *contuzii* (19,1%), urmând apoi localizarea acestora la nivelul abdomenului, lombelor şi bazinului (16,5%) (fig. 4).

Aceste rezultate denotă gravitatea ridicată şi riscul leziunilor organelor vitale toracale (cord, plămâni) şi abdominale (contuzii şi rupturi ale splinei, în special, care pot fi „în doi timp", ducând la şoc prin hemoragie internă şi deces, chiar după o perioadă de timp de la accidentul de trafic rutier) (3, 9, 10, 11).

6. Distribuţia leziunilor în funcţie de gravitate, pentru cazurile de accidente de trafic rutier, luate în studiu a evidenţiat un procent ridicat al traumatismelor cranio-cerebrale şi cranio-faciale (32,4%), urmate de leziuni multiple ale organelor interne (9,3%), iar comoţiile cerebrale şi leziunile intracraniene, de gravitate crescută, fiind întâlnite în 1,8% din situaţii (fig. 5).

Şi alte studii din ţară şi de la nivel mondial pun pe primul loc traumatismele cranio-cerebrale, atât prin frecvenţa lor, cât şi prin gravitatea şi riscurile vitale, care implică o supraveghere şi un tratament imediat şi prompt, în cadrul spitalizării în secţii de neurochirurgie (7,8,9,11).

CONCLUZII

Din punct de vedere al localizării leziunilor, aproape jumătate afectează extremitatea cefalică, un sfert nivelul membrelor şi o cincime torace. Un calcul economic exact al consecinţelor accidentelor de trafic este practic imposibil de realizat, singura certitudine pe care o avem este că tributul plătit de societate, atât medical, cât şi economic, este mult prea mare.

Devine, astfel, necesară instituirea unor programe de prevenţie eficiente la nivel naţional, precum şi adoptarea unor norme care să implice domenii variate ale activităţii umane, identificarea verigilor fragile ale factorilor implicaţi şi eliminarea sau minimalizarea acestora. Considerăm că abordarea multidisciplinară a prevenţiei accidentelor de circulaţie presupune adoptarea unor măsuri *legislative* adecvate şi verificarea respectării lor, a unor măsuri *administrativ - economice* care să vizeze spaţiul rutier, a unor măsuri de *educaţie pentru sănătate,* şi măsuri cu caracter *medical şi psihologic*.

CANCER GENETIC COUNSELING IN EUROPE. PART II: CENTRAL AND EASTERN EUROPEAN COUNTRIES

Aliona Morariu, Alina Manole*, Doina Azoicăi

CANCER GENETIC COUNSELING IN EUROPE (PART II) CENTRAL AND EASTERN EUROPEAN COUNTRIES (Abstract): Hereditary Breast and /or Ovarian Cancer (HBOC) is the leading cancer among women worldwide. Since the discovery of the *BRCA* mutation in the ´90s, several healthcare programs have been established in Western European countries. These programs provide nationwide access to individualized care for families at high risk for HBOC. The genetic counseling starts with mutations screening programs with a guideline for further management of the high-risk group for breast cancer. Unlike Western European in the case of Central and East European countries, genetic testing for mutations in *BRCA1* and *BRCA2* genes is limited due to the high costs not covered by the insurance funds. As an exception between Eastern European countries in the Czech Republic genetic counseling and testing for hereditary breast and/or ovarian cancer is available to all women who are at risk of developing an early onset disease. Because of limited resources the rest of Eastern European countries try to identify some specific solutions for overcome this problem. One solution implemented with success in Poland is to identify founder recurrent mutations in order to offer testing for these recurring mutations to a large population. The high frequency of 3 founder mutations in Polish women supports the implementation of a national program that provides genetic counseling and testing with significantly reduced costs. The same panel of *BRCA1* founder mutations like for Poland, seems to be found in countries from Baltic sea region so the recommendation for national screening for these mutations in HBOC women exist since 2003. The other solution is to offer sequencing of the entire coding region of the gene, which is more precise and covers all mutations, to a highly selected and less numerous populations. For instance, in Romania, free genetic *BRCA1* and *BRCA2* genes testing and counseling is available only in some particular programs conducted in few Medical Centers, but Slovenia implemented a national program for genetic testing and counseling but restricted to EOC patients that were diagnosed with early onset high grade-serous EOC. **Keywords:** HEREDITARY BREAST AND OVARIAN CANCER, BRCA, GENETIC COUNSELING.

Hereditary Breast and/or Ovarian Cancer (HBOC) is the leading cancer among women worldwide. This form is mostly caused by mutations in such genes as *BRCA1* and *BRCA2* and is thought to account for 5 to 10% of all cases of breast cancer (1). Female *BRCA* mutation carriers face an elevated lifetime cancer risk of up to 60% for BC and ovarian cancer (OC) and an age-dependent contralateral BC risk of up to 55% (2, 3). Since the discovery of the *BRCA* mutation in the ´90s, several

health care programs have been established in Europe such as the German Consortium for hereditary BC/OC established by 17 specialized academic centers; The clinical guideline (CG) 41 developed by National Institute for Health and Clinical Excellence (NICE), in UK; or "The Cancer Plan" developed by the French Ministry of Health in coordination with the French National Cancer Institute (Institut National du Cancer / INCa) (4). These programs provide nationwide access to professional, individualized structured care for families at high risk for HBOC including interdisciplinary genetic, clinical and psychological counseling that establish individual risk assessment on the basis of a detailed pedigree and molecular genetic testing for those who fulfill the risk criteria. An intensified BC surveillance program is recommended depending on patients' age, morbidity, and personal preferences, even when individuals test negative for *BRCA1* or *2* mutations if the family history indicates a "high-risk" for BC through pedigree analysis This surveillance is well accepted and includes regular breast MRI, mammography, ultrasound, and a physical exam, all financed by the health insurances systems (5). Prophylactic surgery is also a topic of discussion for *BRCA* mutation carriers (6).

However, experiences from other countries show that not everywhere in the Europe women with HBOC get genetic testing and counseling. In Central and Southeastern European countries, incidence and mortality trends show an increment, due to recent changes in risk factors (smoking, age at menarche, age at first pregnancy, estrogen intake, etc.) (7). The delay in transition and European integration of these countries has reflected also on the status of the investigation of hereditary disorders, including hereditary breast and ovarian cancer (HBOC), resulting in the fact the most of eastern and central European countries are currently without such a national cancer genetic testing and counseling programs (7). The genetic counseling, starting with mutations screening programs is available at some oncological centers, with a guideline for further management of the high-risk group for breast cancer specific for each institution. Unlike Western European in the case of Central and East European countries genetic testing for mutations in *BRCA1* and *BRCA2* genes related to breast cancer, as well as for any other cancer type of cancer, is limited due to the high costs (2,000 €) that is not covered by the insurance funds (8). Moreover, the group of genetic counseling (geneticist or molecular biologist, psychologist, oncologist), is not always available at the Cancer Centers. So, free genetic testing is available only in some particular programs (8).

In this article we aim to describe the current status and trends of cancer genetic testing and counseling programs in several Central and Eastern European countries to raise awareness among physicians and payers, and to propose the most important changes needed to improve oncology care in CEE countries.

Cancer genetic counseling in Eastern European countries

It is difficult to estimate the model of genetic counseling applied in Central and Eastern European countries, particularly because, to our knowledge, data on adherence to the various models are lacking. As in all countries in transition with very limited resources, the introduction of highly sophisticated and very expensive laboratory techniques into clinical practice is always questionable. Due to the lack of hot spots or recurrent mutations in the majority of

geographical areas, direct sequencing of the entire coding region of both *BRCA* genes is strongly recommended for *BRCA* analysis, which would make population-based screening expensive. Because of limited recourses Eastern European countries try to identify some specific solution for overcome this problem. The first solution is to conduct some HBOC genetic screening study in order to identify the recurrent mutations, even less frequent than Israel`s or Iceland`s, in order to offer testing for these recurring mutations to a large population. The second solution is to offer sequencing of the entire coding region of the gene, which is more precise and covers all mutations, to a highly selected and less numerous populations. Identification of BRCA mutation carriers, establishment of spectra and frequency of BRCA mutations, especially in breast cancer patients, together with long-term follow-up of mutation carriers, should allow research on the factors affecting penetrance of BRCA gene mutations. Further, systemic BRCA analysis will enable introduction of clinical management for mutation carriers into the clinical practice, resulting in real benefit for this highly vulnerable part of the population (9).

One of the countries that successfully implemented the first strategy is **Poland**. Three mutations in *BRCA1* (*5382insC*, *C61G* and *4153delA*) are common in Poland and account for the majority of mutations identified to date in Polish breast and breast-ovarian cancer families. It is not known, however, to what extent these 3 founder mutations account for all of the *BRCA* mutations distributed throughout the country (10). This question has important implications for health policy and the design of epidemiologic studies. The high frequency of this mutations in Polish women supports the recommendation to testing for genetic ovarian cancer susceptibility with significantly reduced costs. A national program has been established in Poland that provides genetic counseling and testing services for these 3 mutations to the entire population at no cost to the participants (11). At this moment several Genetic Counseling Units like Warsaw Cancer Center Institute of Oncology offers risk counseling based on the occurrence of cancer in the pedigree. In the families identified with an increased cancer risk, genetic testing is critical for preventive healthcare, including specialized surveillance programs and prophylactic mastectomy and/or oophorectomy, which reduce the risk of breast/ovarian cancer by over 90%. However, according to Polish guidelines and recommendations, the government sponsored surveillance program, which includes annual mammography and breast magnetic resonance imaging, pelvic ultrasonography, and cancer antigen 125 levels, is provided only to women with known pathogenic mutations (12).

The same panel of *BRCA1* founder mutations like for Poland, seems to be found in countries from Baltic sea region. The most frequently detected mutation in this Baltic Sea region is the *c.5266dupC*, found from the Baltic Sea to the Pacific Ocean and from Europe to Siberia (13). The *c.4035delA* (*4154delA*) mutation is the second most prevalent mutation in the Baltic states (13). Despite these founding, what is assuring extremely high cost-effectiveness in identification of individuals with high risk of breast and/or ovarian cancers, was recommended for practical genetic testing purposes since 2003 (13), there is no national program available in these countries at this moment.

As an exception between Eastern European countries genetic counseling and test-

ing for hereditary breast and/or ovarian cancer is available to all women in the **Czech Republic** who are at risk of developing early onset disease. There is access to genetic counselling in all regions of the country and two major molecular genetic laboratories provide *BRCA1* and *BRCA2* testing for eligible women. Specialized preventive care is organized by 2 centers, within the Complex Oncology Treatment Clinic of MMCI in Brno, and the Department of Oncology of the General Faculty Hospital in Prague, however, some patients and their family members are under the care of other oncology departments and clinics (14). Oncologists, gynecologists and geneticists from both centers draw up and publish guidelines for the specialized preventive care of *BRCA1* and *BRCA2* carriers in the Czech journal Clinical Oncology. Since 1999 almost three thousand probands (patients) and two thousands of family members were tested at Masaryk Memorial Cancer Institute (MMCI). The protocol for the *BRCA1* and *BRCA2* carrier's follow-up and for other individuals with high risk of breast cancer was published in 2001 and 2009. The main purpose of these publications was to standardize the prevention within oncology centers and provide to the carriers the most updated preventive procedures.

The first study of 20 **Bulgarian** familial BC patients was performed in 1998 aiming to develop a screening approach for the *BRCA1* gene (15). No mutations but only benign polymorphisms were identified, most likely due to the small sample size, the low stringency of the selection criteria and the lack of complete analysis of *BRCA2*. Up to 2015 no other surveys on *BRCA1/2* mutations in Bulgarian patients with familial BC/OC have been published. The lack of sufficient genetic studies for inherited mutations in *BRCA1/2* genes in the Bulgarian population impedes the introduction of an effective mutation screening that would identify the individuals at high risk in BC/OC families. In 2015, team from Departments of Surgery and General and Clinical Pathology, University Hospital, "Alexandrovska", Medical University of Sofia, and the Clinic of Medical Oncology, Specialized Hospital for Active Treatment in Oncology, Sofia, conduct a genetic analysis for *BRCA1/2* germline mutations in a cohort of 200 Bulgarian women with BC, fulfilling the recognized international criteria. This is the first comprehensive study in Bulgaria aiming to ascertain the contribution of *BRCA1/2* germline mutations to familial BC in the Bulgarian population. The project has been supported by Ministry of Education and Science, Republic of Bulgaria. No other data about genetic counseling programs is available (16).

In **Romania** the first molecular investigation of the role of the *BRCA* genes in breast and ovarian cancer was made in 2010 at "Grigore T. Popa" University of Medicine and Pharmacy, Iasi (17). In 2014, after 10 years of collaborative research with *Jean Perrin Center* from Clermont-Ferrand, France, at "Grigore T. Popa" University of Medicine and Pharmacy Iasi was founded the Department of Oncogenetics. A founded by University program for implementation of efficient and coherent system of HBOC molecular diagnostic, rick evaluation and further ontogenetic counseling and management, using the French model, was conducted in collaboration with *Jean Perrin Center*. The program offers free genetic testing d counseling for the first 100 HBOC families. Another project of *BRCA1* /*BRCA2* testing of 200 women with beast/ovarian cancer was started in

2015 at "Prof. Dr. I. Chiricuţă" Institute of Oncology in collaboration with "Iuliu Haţieganu" University of Medicine and Pharmacy, Cluj-Napoca. This prospective study will enhance the result of germline *BRCA1* /*BRCA2* mutations in Romanian high-risk breast cancer patients (18).

Genetic screening for mutations on inherited breast/ovarian cancer in **Slovenia** started at the Institute of Oncology Ljubljana, in 1999. The first step in implementing a *BRCA1/2* genetic counseling was the approval of the Commission for Medical Ethics at the Ministry of Health, Republic of Slovenia for a study that aim to include into the process of genetic counselling all living patients with epithelial ovarian cancer (EOC) younger than 45 years at the time of diagnosis in the period 1999-2008 according to the data of the Slovenian National Cancer Registry made at the Institute of Oncology Ljubljana (19). The process of genetic counselling included the possibility of genetic *BRCA1/2* testing, with all possible clinical implications offered afterwards. All germinal *BRCA1/2* mutation (*gBRCA1/2m*) positive patients were offered inclusion into the screening and prophylactic program for the high-risk group for breast cancer. In addition, the PARP inhibitor therapy was offered to relapsed *BRCA* positive serous ovarian cancer patients. Following new guidelines of SGO and National Comprehensive Cancer Network (NCCN), genetic counselling is offered now to all EOC patients in Slovenia. However, genetic testing is still restricted to EOC patients that were diagnosed with high grade-serous EOC (20).

CONCLUSIONS

Large differences in cancer epidemiology, in the majority of oncology care parameters and in treatment outcomes, exist between CEE countries and neighboring Western European countries. Since the European Union (EU) is built on the concept of free movement of goods, services, people and capital, the EU aims to safeguard the quality of health care for consumer protection reasons. Delivery of health care is still the responsibility of the individual countries within the EU. Because of the growing mobility of professionals and patients, the EU's mission is to encourage and support progress to ensure high quality and comparable care across Europe. In this condition to accelerate the development of cancer genetic testing and counseling in CEE countries and to reduce the apparent disparities across Europe, in CEE countries a shared set of prioritization criteria would be desirable. Prioritization should be based on considerations of medical benefit; health need and costs and all decisional factors should be included in further discussion and better evidence is needed before clearly defined common recommendations and strategy for improving patient management in all European Union countries. Screening programs for genetic testing of HBOC patients should be implemented, and the results of the research study on local founder mutations should be centrally evaluated and used for increase cost/benefit efficiency of genetic testing programs. Improved education for all involved in oncology care is needed. Special attention should be on training specialists in cancer genetic counseling and management. Also, very important and needed throughout the region is development of clinical guidelines and training for counseling and cancer care management and follow-up of cancer patients and survivors is needed. Countries in the CEE region urgently need to increase investments and make higher allocation of health care budg-

ets for oncology in order to diminish gaps between them and neighboring Western European countries. Implementation of all these measures needs additional EU funds to decrease inequalities in cancer control in Europe.

BREAST CANCER IN WOMEN OVER 60 YEARS OF AGE (Abstract) : The breast cancer is the most frequent malignancy in women over 60 years of age in the developed countries and it represents the second frequent cause of death through malignancies in women. **Material and method** : The study was performed on 63 women over 60 years old diagnosed with breast cancer in an one year period (2006) in our service. The aim of the study is to establish the clinical particularities and the optimal therapeutically management of this disease on elderly women. **Results** : The incidence of the malignancy is high (78% of all cases) in women of 60 to 69 years of age. The most common risk factor revealed in this study is the obesity (33%). The cardiovascular diseases (70%) and the atrophic cervico-vaginitis (43%) are the most frequent associated conditions. The incidence of the low stages of the malignancy is low (14%) and usually the tumors are well differentiated ductal invasive carcinomas (63%). The modified Madden radical mastectomy was performed in most of the cases (75%). **Conclusions** : The breast cancer in elderly women has an incidence peak at the age of 60 to 69 years . Despite the numerous associated conditions the surgical treatment remains the most effective therapy. **Key words** : BREAST CANCER, ELDERLY WOMEN, RISK FACTORS, THERAPEUTICALLY MANAGEMENT

Cancerul mamar reprezintă cea mai frecventă afecţiune malignă a femeilor din ţările dezvoltate şi constituie a doua cauză de mortalitate prin cancer în rândul femeilor cu vârsta de peste 60 de ani (1).

Cancerele ginecologice la persoanele vârstnice sunt diagnosticate, de obicei, în stadii avansate, deoarece acestea nu beneficiază, de cele mai multe ori, de consultaţii ginecologice de rutină în scopul realizării unui screening oncologic genital.

Incidenţa mai crescută a malignităţilor la pacientele vârstnice se explică prin mai multe ipoteze :

- mecanismele de reparare a ADN-ului sunt afectate în mod negativ odată cu avansarea în vârstă ; în consecinţă celulele îmbătrânite nu mai controlează replicarea ADN-ului, fapt ce duce la aneuploidie şi proliferare necontrolată. În cazul persoanelor tinere aceste anomalii declanşează mecanisme ce duc la moartea celulei afectate (apoptoză) (2) ;
- scăderea funcţiilor sistemului imun, în mod special a imunităţii mediate celular (3) ;
- patologia malignă diagnosticată la persoanele vârstnice apare , deobicei , după o lungă perioadă în care factorii de risc au acţionat favorizând apariţia bolii. Acest fapt coroborat cu ipotezele mai sus menţionate determină apariţia cu o frecvenţă mai crescută a maladiei neoplazice la persoanele vârstnice (2,3).

Agresivitatea relativ mai scăzută a neoplasmelor la pacientele vârstnice se poate explica prin teoria neoangiogenezei mali-

gne, aceasta fiind mai redusă la pacienta vârstnică, limitând rata de creştere tumorală.

Femeile cu vârsta de peste 60 de ani deţin o treime din totalul cazurilor de cancer mamar şi jumătate din decesele datorate acestei afecţiuni. Studiile efectuate relevă faptul că femeile în vârstă au frecvent tipuri histologice mai favorabile, nivele mai mari de receptori estrogenici si progesteronici, rată de creştere tumorală mai scăzută şi mai puţine metastaze (3).

Factorul vârstă este unul dintre cei mai importanţi factori de risc pentru cancerul mamar. Riscul ca o femeie cu vârsta sub 40 ani să dezvolte cancer de sân este mai mic de 0,5%, acest risc crescând de peste 20 de ori la aceeaşi femeie(10%) la vârsta de 90 ani (4).

Depistarea precoce a neoplaziei mamare prin efectuarea mamografiei ca metodă de screening ar reduce considerabil stadiul neoplaziei mamare în momentul diagnosticării acesteia. Mortalitatea prin cancer mamar la 10 ani s-ar reduce cu 25-30%. Din păcate, chiar şi în ţările dezvoltate, screeningul prin mamografie al cancerului mamar la persoanele vârstnice este deficitar. În USA peste 50% din femeile cu vârsta de peste 60 de ani nu au efectuat vreodată o mamografie (4,5).

Mamografia, ca singură metodă exploratorie de screening, nu diagnostichează aproximativ 10-15% din cancerele mamare (6).

Asociaţia Americană de Geriatrie recomandă ca şi metode de screening mamografia şi examenul clinic al sânului , care trebuiesc efectuate anual până la vârsta de 75 de ani şi după această vârstă se recomandă ca mamografia să fie efectuată la 2 ani iar examenul clinic al glandei mamare anual (7,8).

MATERIAL ŞI METODĂ

Lotul de studiu este constituit din 63 de cazuri reprezentând pacientele cu vârsta peste 60 de ani diagnosticate în perioada 1 ianuarie-31 decembrie 2006 cu neoplazie mamară în Clinica a II-a Obstetrică-Ginecologie, Spitalul de Obstetrică-Ginecologie "Cuza-Vodă" Iaşi.

Lotul principal, în funcţie de criteriul vărstă, s-a subdivizat în 3 subloturi - cu vârsta cuprinsă între 60-69 ani, 70-79 ani şi peste 80 de ani.

Factorii urmăriţi în studiu sunt: vârsta, mediul de provenienţă, factorii de risc, stadiul bolii, forma anatomo-patologică, prima secvenţă terapeutică, tipul intervenţiei chirurgicale, durata medie de spitalizare, patologii frecvent asociate.

REZULTATE

Incidenţa maximă a neoplaziei mamare se află în subgrupul pacientelor cu vârsta între 60-69 ani – 49 cazuri, restul cazurilor fiind distribuite astfel: 13 cazuri - subgrupul 70-79 ani, 1 caz – subgrupul pacientelor cu vârsta peste 80 de ani. Mediul rural prezintă o incidenţă uşor mai crescută comparativ cu cel urban (53,96% vs 46,04%).

Dintre factorii de risc obezitatea a fost cea mai frecventă manifestare întâlnită (33,3%), fiind urmată în ordinea frecvenţei de menopauza tardivă, lipsa alăptatului la sân, antecedente familiale de neoplazie mamară, menarha precoce

Patologiile asociate, mai ales cele cardiovasculare, pot reprezenta la acest grup de vârstă un obstacol în instituirea imediată a terapiei bolii canceroase, necesitând în primul rând echilibrarea acestora.

Cervico-vaginita atrofică a fost întâlnită în

TABELUL I
Factori de risc

Factor de risc	Număr cazuri
Obezitatea	**21**
Menopauza tardivă	**8**
Lipsa alăptatului la sân	**6**
Antecedenta familiale de neoplazie mamară	**5**
Menarha precoce	**5**
Nuliparitatea	**4**

TABELUL II
Patologie asociată

Patologie asociată	Sublot I 60-69 ani	Sublot II 70-79 ani	Sublot III >80 ani
Cervico-vaginita atrofică	18	8	1
H.T.A.	14	7	1
Cardiopatie ischemică	10	6	1
D.Z.	5	2	0
Prolaps genital	3	2	0
Varice membre inferioare	3	1	0

cele mai multe cazuri (42,85%), fiind urmată de bolile cardio-vasculare (cardiopatia ischemică - 27%, HTA - 35%), diabet zaharat (11,1%), prolaps genital (7,93%), varice la nivelul membrelor inferioare (6,34%).

Din punct de vedre anatomo-patologic carcinomul invaziv ductal domină ca frecvenţă –(63,49%), fiind urmat în ordine de carcinomul invaziv lobular (25,41%), mastita carcinomatoasă (6,34%) şi de carcinomul microinvaziv ductal (4,76%).

Stadiul neoplaziei în momentul diagnosticului a fost avansat în cele mai multe cazuri, stadiul III a fost întâlnit cel mai frecvent (34,9%), excepţie făcând sublotul pacientelor cu vârsta cuprinsă între 70-79 ani în care stadiul IV a fost întâlnit cu aceeaşi frecvenţă ca şi stadiul II (4 cazuri). Stadiile incipiente ale neoplaziei mamare (0/I) au fost diagnosticate în 9 cazuri (stadiul 0 – 3 cazuri, stadiul I – 6 cazuri) .

Conduita : tratamentul chirurgical a fost instituit de primă intenţie în cele mai multe cazuri (54,14%), factorul vârstă, în absenţa unei patologii grave asociate, neinfluenţând intervenţia chirurgicală, în restul cazurilor s-a optat în 39,69% din cazuri ca primă intenţie terapeutică polichimioterapia, iar în 3,79% din cazuri radioterapia.

Durata medie de spitalizare a pacientelor, în special a celor operate, a crescut uşor odată cu vârsta acestora (de la 11 zile în sublotul celor cu vârsta între 60-69 ani la 14 zile în sublotul pacientelor cu vârsta cuprinsă între 70-79 ani).

DISCUŢII

Variantele tratamentului chirurgical sunt multiple, mulţi practicieni optând în cazul pacientelor în vârstă cu cancere mamare în stadii incipiente pentru excizia sectorială în limite de siguranţă oncologică urmată de evidare ganglionară axilară şi radioterapie postoperatorie. O altă variantă menţionată în literatură constă în hormonoterapie (Tamoxifen, Raloxifen) ca unic tratament pentru pacientele vârstnice cu cancere mamare cu receptori estrogenici prezenţi şi cu patologii asociate ce prezintă un risc anestezic şi chirurgical crescut (7).

Conduita noastră a constat într-o abordare mai radicală a bolii canceroase în cazul pacientelor la care starea generală a permis acest lucru. Pornind de la premiza că neoplazia mamară prezintă un grad crescut de multicentritate (până la 70% în cancerele lobulare şi până la 40% în cancerele ductale) (3) mastectomia radicală tip Madden cu limfadenectomie axilară a fost metoda de elecţie în tratamentul cu scop curativ al cancerului mamar, constituind 75% din intervenţiile chirurgicale practicate. La mastectomie tip Pattey cu limfadenectomie axilară s-a recurs în 5,5% din cazurile operate, iar mastectomia simplă s-a practicat în 19,5% din intervenţii.

Bolnavele în vârstă cu cancer mamar beneficiază de tratament multimodal. Pentru stadiile I-II secvenţa chirurgicală este prima metodă terapeutică. Pentru stadiile III-IV radioterapia este prima metodă terapeutică urmată de mastectomia “de curăţire”. Mas-

tectomia simplă este indicată numai cazurilor la care terenul nu permite o operaţie de durată.

Complicaţiile tratamentului chirurgical sunt relativ rare. Complicaţiile intraoperatorii constau din leziuni neurovasculare şi ale pleurei. Leziunile nervului Charles Bell şi subscapular nu sunt urmate întotdeauna de o atitudine vicioasă a omoplatului sau sechele respiratorii. Leziunile pachetului vascular axilar sunt rare şi obligă la sutură vasculară şi nu ligatură. Complicaţiile postpoperatorii imediate pot fi reprezentate de: hematoame, colecţii limfatice în regiune axilară, supuraţii, dezunirea suturilor, tromboflebita venei axilare (9). Lotul studiat nu a prezentat complicaţii intraoperatorii sau postpoperatorii imediate.

Complicaţiile postoperatorii tardive constau în: edemul important al membrului superior de partea sânului operat –cea mai redutabilă complicaţie a intervenţiilor radicale, având cauze multiple: obstrucţie venoasă sau limfatică, scleroză cicatricială (9). În lotul studiat s-au semnalat 2 cazuri care au prezentat un edem moderat al braţului datorat unei tromboflebite de venă axilară. Sub tratament anticoagulant evoluţia a fost favorabilă în ambele cazuri.

Complicaţiile postoperatorii datorate decompensării patologiei preexistente au constat în 3 cazuri în dezechilibrarea diabetului zaharat, 2 cazuri - agravarea simptomatologiei datorate cardiopatiei ischemice, 4 cazuri - agravarea hipertensiunii arteriale, 2 cazuri - tromboflebită profundă membre inferioare. Evoluţia acestor cazuri a fost favorabilă sub tratament, nu s-a înregistrat niciun deces în perioada postoperatorie.

CONCLUZII

Cancerul mamar prezintă o creştere a incidenţei odată cu avansarea în vârstă. Pe lotul studiat, paciente cu vârsta peste 60 de ani, incidenţa maximă a neoplaziei regăsindu-se în subgrupul pacientelor cu vârsta între 60 şi 69 de ani.

Stadiul bolii în momentul diagnosticului este, de cele mai multe ori, avansat şi creşte odată cu înaintarea în vârstă.

Formele anatomo-patologice întâlnite la aceste vârste nu diferă semnificativ ca frecvenţă şi tip în comparaţie cu cele întâlnite la vârste mai tinere, agresivitatea bolii canceroase neprezentând o creştere la persoanele vârstnice.

Bolile cardiovasculare (H.T.A., cardiopatia ischemică) domină ca frecvenţă şi severitate patologia asociată bolii canceroase la acest grup de vârstă.

Obezitatea, factor de risc al majorităţii neoplaziilor ginecologice, este o condiţie patologică frecventă.

Tratamentul chirurgical, în lipsa comorbidităţilor severe şi coroborat cu stadiul bolii, rămâne secvenţa terapeutică principală, factorul vârstă necontraindicând aplicarea acestuia.

THE ROLE OF INTERLEUKIN 10 (rs1800872) AND HEAT SHOCK PROTEIN 70-2 (rs1061581) GENES IN THE MECHANISMS OF COLIENTERITIS DEVELOPMENT (Abstract): *E. coli* is one of the commonest causes of diarrhea worldwide responsible for 20-50% of all infectious diarrheas. Genetic background of the condition, including the possible role of IL-10 (rs1800872) and thermal shock protein 70-2 (rs1061581) genes remains unclear. **Aim:** To find the possible role of IL-10 (rs1800872) and Heat Shock Protein (HSP) 70-2 (rs1061581) genes in the mechanisms of colienteritis pathogenesis. **Material and methods:** 95 patients with diarrheal escherichiosis and 30 practically healthy individuals (control) participated in the study. Gender composition presented with 62 women (65.26%) and 33 men (34.74%), mean age – 38.66±3.11 yrs. The single nucleotide polymorphisms (SNP) of HSP70-2 (A1267G) and IL-10 (C-592A) genes were studied in PCR. **Results**: Among patients, IL-10 (rs1800872) and HSP70-2 (rs1061581) genetic mutations were observed with frequencies of 9.47% and 3.16%, respectively, compared to absence in control. Allelic distribution of HSP70-2 gene's 1267G>A SNP showed 2.62 times G-allele domination over A-allele ($p<0.001$): among patients by 43.16% ($\chi^2=70.78$; $p<0.001$), and in control by 50.0% ($\chi^2=30.0$; $p<0.001$), with insignificant excessive heterozygosity, not disturbing expected Hardy-Weinberg's equilibrium. Allelic distribution of IL-10 gene's C-592A SNP shows C-allele 2.9 times dominated ($p<0.001$) in general population: among patients by 43.16% ($\chi^2=70.78$; $p<0.001$), in control – by 66.66% ($\chi^2=53.33$; $p<0.001$), with preserved population equilibrium. **Conclusions**: Mutant A-allele of the IL-10 (rs1800872) gene associates with almost twice increased colienteritis risk in observed population [OR=1.98; 95%CI OR=1.0-4.20; p=0.046], with protective role of wild C-allele [OR=0.50; 95%CI OR=0.24-1.01; p=0.058]. HSP70-2 gene's SNP (rs1061581) does not associate with colienteritis risk. **Keywords:** COLIENTERITIS, DIARRHEA**,** PATHOPHYSIOLOGY, INFLAMMATION, SINGLE NUCLEOTIDE POLYMORPHISM, HSP70-2 (RS1061581) GENE, IL-10 (RS1800872) GENE, ALLELE, RISK.

According to WHO's Diarrheal disease Fact sheet and Global Burden of Diseases, about 1.7 to 5 billion cases of diarrhea occur per year worldwide. Total deaths

from diarrhea are estimated at 1.26 million in 2013, down from 2.58 million in 1990. In 2010, it is the second most common cause of deaths (0.76 million or 11%) in children younger than five years (1, 2).

Colienteritis is one of the commonest causes of diarrhea with incidence of 20-30 cases per 100,000 individuals in developed countries and is caused by pathogenic strains of *Escherichia coli* (3). The pathophysiology of colienteritis clinical manifestations to some extend depends on *E. coli* variant (enterotoxigenic, enteroinvasive, enteropathogenic, enterohemorrhagic, and enteroaggressive). However, major pathogenetic mechanisms of colienteritis development are universal, involving pro- and anti-inflammatory cytokines (4). Genetic background for intestinal disorders underwent explosive development in recent years, mainly focusing on microbiome and its relationship with metabolome and proteome. Genetic background for digestive system diseases as well as other inflammatory conditions is well established, proving associations of several genes' single nucleotide polymorphisms (SNPs) with hepatitis, metabolic syndrome (5, 6) . However, lesser attention was paid to genetically determined susceptibility to *E. coli* emphasizing development of intestinal and systemic inflammation. Our attention attracted genes regulating IL-10 and Heat Shock Protein (HSP) synthesis. Both IL-10 and HSP play an important role in regulating systemic inflammation, though the role of respective genetic mechanisms in colienteritis requires clarification. Therefore, *the aim of this study* was to find the possible role of IL-10 (rs1800872) and Heat Shock Protein (HSP) 70-2 (rs1061581) genes in the mechanisms of colienteritis pathogenesis.

MATERIAL AND METHODS

The study involved 95 individuals with escherichiosis (mean age 38.66±3.11 yrs. ranging from 25-52 yrs.), among them 62 (65.26%) female and 33 (34.74%) male patients. Colienteritis diagnosis was based on clinical symptoms, history, laboratory findings, including microbiology and coded as A04.8-A.04.9 in IDC-10. Enteropathogenic, enteroinvasive, enterohemorrhagic *E. coli* , hemolytic (*E. coli* Hly+), and lactose-negative *E. coli* were isolated and identified. Identification of other possible intestinal pathogens led to exclusion from the study group. Control group formed by 30 practically healthy individuals of respective age and gender without any acute or chronic inflammatory processes and no antibacterial drugs intake in any form for at least 6 months prior to the study.

This study *conforms to international bioethical standards* (European Convention on Human Rights and Biomedicine, the Declaration of Helsinki of the World Medical Association on ethical principles of scientific medical research involving human subjects, GCP, EUC directive #609, etc.) and approved by Commission for Bioethics in Research of the Bukovinian State Medical University, Ukraine. All patients signed written permissions and obtained full information about the study prior to participation.

Polymerase chain reaction (PCR) was used to study the polymorphism of HSP70-2 (A1267G, rs1061581) and IL-10 (C-592A, rs1800872) genes. DNA was isolated from peripheral venous blood lymphocytes using a set of DNA-sorb-V reagents. PCR was performed using Taq-DNA-polymerase and following specific primers for HSP70-2 (5′-CATCGACT TCTACACGTCCA-3′ – *forward* and 5′-CAAAGTCCTTGAGTCCC AAC-3′ – *reverse*) gene (7), and IL-10 (5′-

CCTAGGTCACAG TGACGTGG-3′ – *forward* i 5′-GGTGAG CACTACCTGA-CTAGC-3′ – *reverse*) gene (8).

Allele discrimination of the HSP70-2 gene was performed using restriction endonuclease PstI (Fermentas, Lithuania). The products of DNA amplification (amplicons) of the C-592A SNP of the IL-10 gene and those of the restriction of HSP70-2 gene A1267G SNP were separated in horizontal electrophoresis in a 3% agarose gel concentrated with 4 μL of ethidium bromide for 45-60 minutes. Visualization using transluminator with addition of GeneRuler 50 bp DNA Ladder (Thermo Scientific, USA) molecular weights marker. Visualized images analyzed in *SnapGene* and *Vitran* software packages.

Statistical processing was carried out using the *MS Excel, Primer of Biostatistics 6.05* and *Statistica 7.0* software. Logic regression was used for establishing genetic dependencies.

RESULTS

No statistically reliable differences in genotypes and alleles of both HSP70-2 (A1267G) and IL-10 (C-592A) genes' SNPs relative frequencies (tab. I-II) between study and control groups were observed. In general population, from 190 identified alleles, in both control and study groups HSP70-2 (rs1061581) gene's G-allele dominated 2.52 and 3 times ($p<0.001$), and IL-10 (rs1800872) gene's C-allele dominated 2.52 and 5 times ($p<0.001$), respectively. Distribution of HSP70-2 gene's 1267A→G and IL-10 gene's C-592A SNPs in studied cohort meets the Hardy-Weinberg equilibrium ($p>0.05$) with a slight excess of heterozygosity, which generally does not disturb the population balance.

Colienteritis risk emphasizing HSP70-2 (rs1061581) SNP is presented in table III depicting the fact that polymorphic variants of HSP70-2 gene may not be additional risk or protection factors for colienteritis in general observed population.

Epidemiologic analysis of coli enteritis risk associations with IL-10 gene's (rs1800872) genotypes is presented in table IV. Minor A-allele associates with almost double increased colienteritis risk in general population [OR=1.98; 95%CI OR=1.0-4.20; p=0.046] with marginal protection role of IL-10 gene's C-allele [OR=0.50; 95%CI OR=0.24-1.01; p=0.058].

DISCUSSION

Naturally, colienteritis pathophysiologic mechanisms studies are focused primarily on microbiologic factors, which definitely have a meaning. Following contamination by similar pathogen, presence of similar concomitant environmental, age and gender associated risk factors, the response of the immune system differs, as well as the severity of the disease, the appearance of complications. It is likely that an important role in the immunological response to the

pathogen belongs to non-specific immune resistance provided by neutrophils and is subject to mRNA expression of protein activity encoded by the corresponding genes. One of the molecular systems for protecting cells from cytotoxic reactions is HSP. Previous studies proved the protective role of HSP70 on intestinal cells (9). Tahara *et al.* found that HSP70-2 gene associated with a reduced risk of gastric cancer in older persons infected with H. pylori (10) but increases the risk of duodenal ulcer (11). J.A. Lin et al n showed that A1267G SNP of this gene (rs1061581) does not associate with the development of spondylitis in the Chinese population (12), vulvaginitis in adolescent girls of Northern Bukovina (8), but increases the risk of intestinal perforations, formation of fistulas and abscesses in patients with Crohn's disease in Japanese and European populations (13). This is the first available study of the HSP70-2 gene's A1267G SNP associations with the colienteritis. However, it shows that this SNP of the HSP70-2 gene is not an additional risk factor for colienteritis.

The IL-10 gene in humans is highly polymorphic and at the promoter region several single nucleotide polymorphisms have been described. In individual studies, an association was established between the C592A polymorphism of the IL-10 gene and the onset of coronary heart disease in people younger than 45 years old (14); with higher serum IgE levels in schistosomiasis (15) among the Brazilian population (in mutation A-allele carriers); osteoarthritis severity with diabetes mellitus and obesity (7). In this study we found almost double increase in the risk of colienteritis only in the carriers of the mutational A-allele of the IL-10 gene (rs1800872). Other researchers did not establish links between the studied IL-10 gene SNP with the appearance and severity of several infections including leprosy (16) and viral hepatitis B (17). Valença *et al.* observed no association between the polymorphisms of the IL-10 gene (G1082A / -C819T / -C592A) and the regression of periportal fibrosis after specific treatment for schistosomiasis (18).

CONCLUSIONS

In the observed colienteritis patients, mutations of IL-10 (rs1800872) and HSP70-2 (rs1061581) genes in the homozygous state occur at frequencies of 9.47% and 3.16%, respectively, compared to the absence in control. IL-10 (rs1800872) and HSP70-2 (rs1061581) genes' relative frequencies of alleles did not differ significantly between patients and control.

Mutant A-allele of the IL-10 (rs1800872) gene associates with almost twice-increased colienteritis risk in observed population, with protective role of wild C-allele. Polymorphic variants and alleles of the HSP70-2 (rs1061581) gene are not an additional risk factors for colienteritis in the examined population.

THE ALTERNATIVE METHOD FOR DETECTING DENTAL CARIES USING AN OPEN SOURCE SYSTEM ARDUINO (Abstract): **Aims:** Developing an instrument based on the electrical impedance measurement for dental caries detection and transmission of the result on a fast access device (laptop, tablet and smart phone). **Material and methods:** The system is based on a microcontroller as an Open Source Hardware and an easy to use Open Source Software. The hardware architecture contains signal collection electrodes for resistance measurement of tooth, a microcontroller with Bluetooth data communication and a human machine interface (HMI) with Bluetooth interface and software for data visualization. **Results:** The measured impedance value is used to classify caries types. The extracted features results are showed as a text that suggests the diagnosis. **Conclusions:** The instrument is very useful for fast evaluation of dental health. The system has low power consumption and is very easy to operate with it. **Keywords:** INSTRUMENTATION, DENTAL DECAY, OPEN SOURCE, IMPEDANCE MEASUREMENT.

Every biological material possesses its own electrical signature. When a current pass through this biological material, it will produce an effect on the impedance (1, 2).

The technique of electrical impedance measurements is a promising alternative method for occlusal caries diagnosis. It was described as an original method in 1951, and then used in 1980: Vanguard Electronic caries detector (Massachusetts Manufacturing Corporation, Cambridge) and Caries Meter L (GC International Corporation Interleuvenlaan, Leuven). In 2001 there was made a device for the measurement of the electrical impedance of the hard-dental tissues which was verified in the Cariology laboratory from the "Grigore T. Popa" University of Medicine and Pharmacy Iasi, with the purpose of detecting occlusal caries in incipient phases (3). Then in 2011 it has been created a virtual instrument used to diagnose dental caries using NI data acquisition device and LabVIEW software (4).

Especially in children and adolescents, crack cavities represent 80% of the untreated cases. These are often hidden by an intact enamel layer. Conventional methods of detecting hidden caries are not safe enough in these situations.

There are three directions that influence

the development of medical instruments and establish an early position in a very competitive market: producing safe, high-quality devices for patient care, reduced development time and low-cost system.

It is very difficult to design a medical product that has features and capabilities necessary to be used by a particular customer. To overcome this challenge, we need a new approach that allows increased modularity of design complexity, while permitting the implementation of innovative ideas from non-technical experts. Also, the new trend in Open Source encourages the researchers to develop instruments using open hardware at low cost and free open software (5). Open source systems are widely used in various domains. Some authors are using it for ECG measurements, smart sensors or intelligent home (6), (7).

In recent years, several research groups started to investigate alternative systems for monitoring dental diseases. In this paper, we present an instrument for early detecting dental decay, based on open-source electronics prototyping platform, flexible, easy-to-use hardware and software.

MATERIAL AND METHODS

In our days, the modern microcomputer technologies allow us to simple install various data acquisition systems by using friendly open hardware and open software.

The developed instrument is working with low frequency while out-of-phase component is negligible, and we can use the term resistance. We chose to use a sine wave signal with a frequency of 400 Hz and effective value of 1 μA generated on an analogical output channel of the microcontroller (8, 9). On the output analog channel, we used an electronic passive low-pass RC filter of first order. One simple low-pass filter circuit consists of a resistor in series with tooth impedance and a capacitor in parallel with tooth impedance. We use a combination of resistance (R) and capacitance (C) in order to give the value of 400 Hz for generated frequency (C=100 nF and R=3.98 kΩ). The break frequency, also called cutoff frequency (f_c) is determined by the time constant τ:

$$t = RC \quad (1)$$

$$f_c = \frac{1}{2\pi\tau} = \frac{1}{2\pi RC} \quad (2)$$

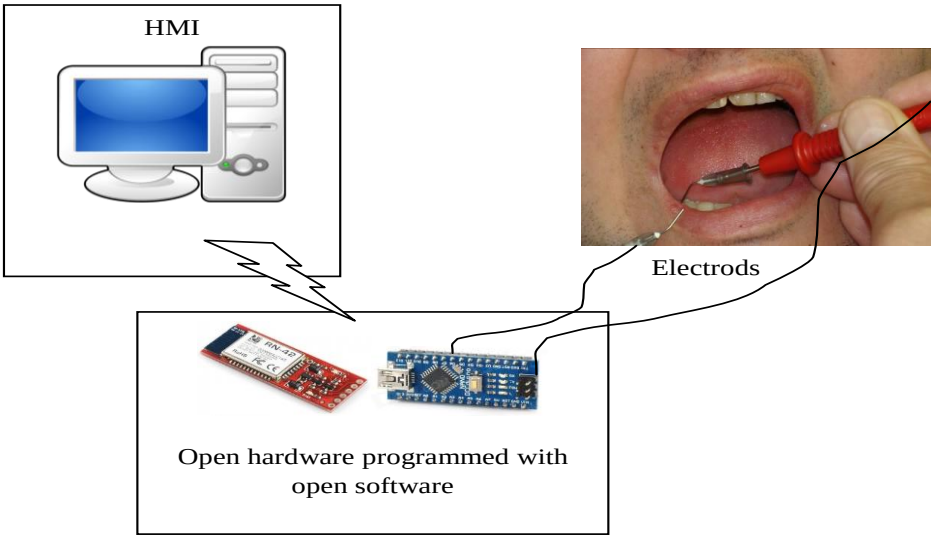

Fig. 1. The hardware architecture of detecting dental decay instrument

The developed system architecture consists of the following elements: signal collection electrodes, the microcontroller with Bluetooth data communication and human machine interface (fig. 1).

Signal collection electrodes for resistance measurement of tooth, active electrode, are applied in the mouth: the active electrode on the tooth and the neutral one on the lip, using single use sterile probes with equal and negligible resistance (R=0.914 Ω). The instrument would not produce pain due to the extremely low generated current.

The microcontroller with Bluetooth data communication was designed to be small so that it fits into a mobile device like a pen which would give the dentist more freedom of handling. We use Arduino micro and RN42 Bluetooth module.

The third element is the human machine interface (HMI) with Bluetooth interface and software for data visualization, represented by a laptop with Java technology-based software.

RESULTS

We use open software like Arduino IDE to program the microcontroller and Java for desktop applications. The implemented firmware is made for the low and high level implemented software. In Arduino IDE we set the functionality of the microcontroller:

1) setup serial communication and pins communication;

2) wait for serial port configuration from desktop application;

3) generate sinusoidal signal over PWM (Pulse Width Modulation) output;

4) acquire data from electrodes throughout analogue input channel;

5) voltage calculus;

6) resistance calculus starting from read voltages.

The instrument was calibrated against standard resistors and the linearity is relatively constant over the full scale (fig. 2).

$R = a \cdot U^3 + b \cdot U^2 + c \cdot U + d$ (3) where the constants a, b, c, d take the values: $a = -3 \cdot 10^{-5}$, $b = 1{,}54 \cdot 10^{-2}$, $c = 5{,}55 \cdot 10^{-1}$, $d = -8{,}062 \cdot 10^{-1}$.

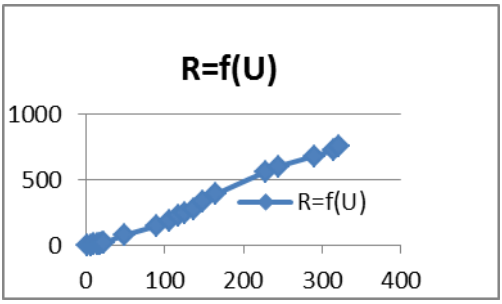

Fig. 2. Calibration graph

7) classify caries types using calculated impedance as shown in the paper;

8) send data over Bluetooth.

The desktop application made in Java software as a human interface, that provides setup communication parameters and has main function to show and save data, which is after sent to the instrument (fig. 3).

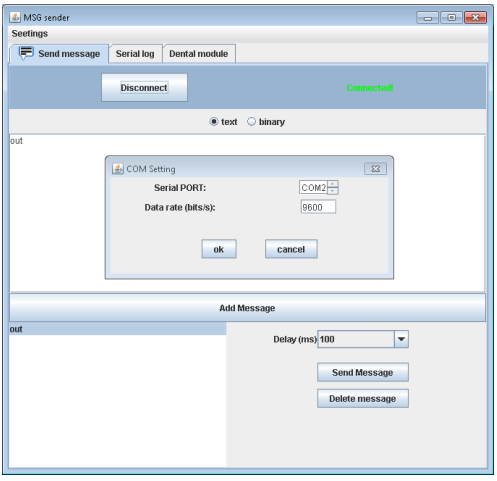

Fig. 3. Java application software - Settings

Measured impedance value is used to classify caries types. The extracted features results

are shown as a text that suggests the diagnosis. Depending on the impedance value Z, the displayed text will be different. An example is showed in the figure 4.

By using "Serial log", the dentist can check and view the history measurement (fig. 5).

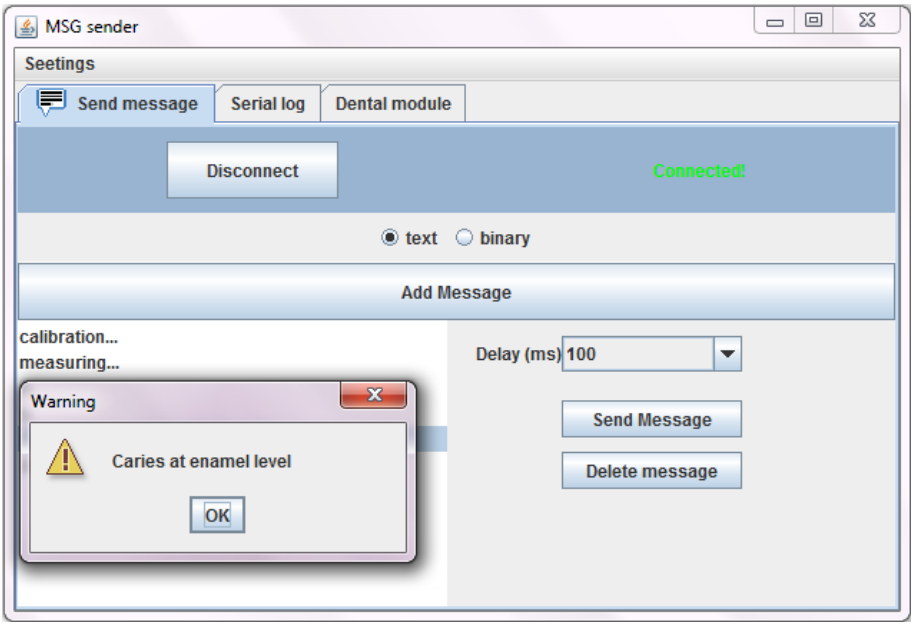

Fig. 4. Java application software – Warning message

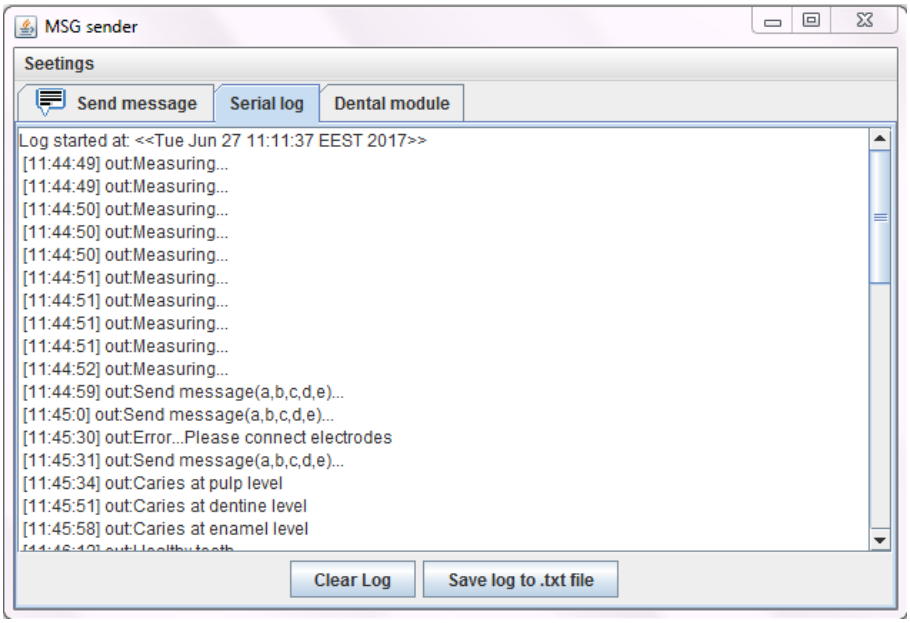

Fig. 5. "Serial log" - the history measurement

The device has been tested in a Dental Office, on a group of 18 subjects in order to put the right diagnosis. The measurements were taken not only on decayed teeth, but also on healthy ones. The results were also validated by a dentist, who diagnosed the subjects through classical methods.

DISCUSSION

Starting from the research of Mayuzumi and Suzuki (10), our instrument software is based on the measurement of electrical impedance of dental tissues. When a sinusoidal current cross the dental tissue with 400 Hz frequency, the impedance is more than 600 KΩ. It has been observed that the electrical impedance decreases as the dentin caries progresses, so the impedance of enamel caries presents values between 250 and 600 KΩ and in dentin caries, the impedance varies between 15 and 250 KΩ, depending on the depth of decay (fig. 6).

The term impedance is used to describe the resistance to an alternating current at a certain frequency. The total impedance of the circuit is the sum of the components in phase and out of phase. Due to the fact that, the frequency in the device is small, the out of phase component is negligible, and the term resistance can be used.

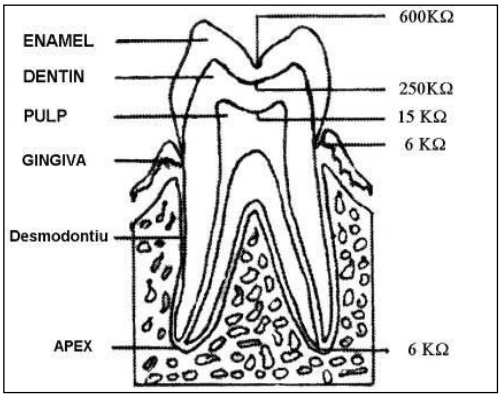

Fig. 6. Impedance values representation depending on the decay type

The classification of caries types using calculated impedance:

- Z = 0÷15 kΩ - "Caries at pulp level"
- Z = 15÷250 kΩ - "Caries at dentine level"
- Z = 250÷600 kΩ - "Caries at enamel level"
- Z > 600 kΩ - "Healthy tooth"
- Z < 0 – "Error" (10).

By tightly integrating hardware, software, validation, and reporting tools, the Java technologies provide the best solution for rapidly developing and testing medical devices and allow an expert in designing integrated systems, to accelerate the development of medical devices.

CONCLUSIONS

Starting from the theory underlying the use of electrical resistance in the diagnosis of caries (that enamel is a good insulator, but during the caries process, porosity formed in tissue which will be filled with water and ions saliva, acting like networks conductive, causing reduced electrical resistance), we formed an instrument which measures the resistance and that can provide us to give a diagnosis.

The device is easy to use by the dental practitioner and has technical advantages in comparison with other techniques used so far because the results are transmitted via Bluetooth to a device much easier to follow (laptop, tablet and smartphone).

The work presented is also a part of the open source systems trend, in a sense of reducing the costs, flexibility and biological signal processing systems modularization. Using an HMI and a low-cost hardware to process and measured signals, our solution allows a rapid development of the product, resulting in quicker deployment. The software that we developed represents an important tool, which helps dentists to speed up diagnosis.

Comparing with other diagnosis methods, our measurement method for the electrical resistance of the tooth seems to offer the highest hope for achieving reliable, accurate detection of the earliest stages of enamel demineralization. The time for taking measurement data is shorter comparative to other methods.

NEWS

CHARACTERIZATION OF LARYNGOTRACHEAL MICROBIOTA IN PATIENTS WITH LARYNGOTRACHEAL STENOSIS

Knowing that microbial flora may play a role in mucosal inflammation, Hillel AT *et al*. studied the microbiota associated with laryngotracheal stenosis of various etiologies, in adults. The study showed significant differences in microbial community composition between scar and nonscar samples, as well as depending on etiology and sample site. Thus, scar samples and samples taken from the glottis region had decreased microbiota diversity. Members of the family *Moraxellaceae*, including *Moraxella and Acinetobacter*, were associated with idiopathic scar samples. There was an inverse correlation between Prevotella and Streptococcus among samples. The study concluded that these differences may influence the management of the disease (Hillel AT, Tang SS, Carlos C, Skarlupka JH, Gowda M, Yin LX, Motz K, *et al.* Laryngotracheal Microbiota in Adult Laryngotracheal Stenosis. *mSphere*. 2019; 4(3). pii: e00211- 19. doi: 10.1128/mSphereDirect.00211-19).

MECHANICAL VIBRATION APPLICATION AND LOW-LEVEL LASER THERAPY TO ACCELERATE ORTHODONTIC TOOTH MOVEMENT, AN OVERVIEW

MECHANICAL VIBRATION APPLICATION AND LOW-LEVEL LASER THERAPY TO ACCELERATE ORTHO-DONTIC TOOTH MOVEMENT, AN OVERVIEW (Abstract): It is well-known that in the last decades, orthodontic treatments are successful not only for children and young people, but also for adults. One of the drawbacks of classical orthodontic treatments, reported by patients, is the prolonged period of the orthodontic treatment. In this context, specialty research focuses on the improvement and successful application of devices for accelerating orthodontic treatments, which would allow a considerable reduction in treatment time. From the available devices that can accelerate the rate of orthodontic tooth movement, two completely non-invasive devices, that need no individualization, have a wide addressability and have been discussed more and more frequently in the literature are, Low Level Laser Therapy (LLLT) and mechanical vibration application. Being relatively new techniques in orthodontics a need is felt to pay more attention to the understanding of the basic principles of using these methods and to identify and summarize the main characteristics of these two devices. The aim of this overview study is to lead to a better understanding of the possibilities of using these devices in day to day practice. This paper presents some of the characteristics of these methods that we found through the literature searches conducted for reviews and research articles related to vibrational devices and LLLT that accelerate orthodontic tooth movement. **Keywords***:* ORTHODONTICS, TOOTH MOVEMENT, LOW LEVEL LASER THERAPY, VIBRATIONAL DEVICES.

In orthodontics, in order to achieve tooth movement a mechanical stimulus is introduced by placing fixed appliances on the teeth (1). The fixed orthodontic appliances are bonded to the tooth surfaces that were previously conditioned in order to facilitate adhesion (2) using various materials (3). Then certain forces are applied to the dentoalveolar complex in order to realize these movements (1). Applying external physical force will lead to the inflammation or ischemia of the periodontal ligaments and bone remodeling, this phenomenon with inflammatory reactions can sometimes be painful for the patient. The time needed for a classic, fixed orthodontic treatment is around 2-3 years and a prolonged treatment can also lead to complications. Reducing the duration of orthodontic treatment can decrease the incidence of side-effects, there-

fore create more comfort for patients (4). Knowing the importance of the correlations between dental, skeletal and chronological age in orthodontics (5), the initial situation, treatment evolution and outcome need to be evaluated and stored using the currently available digital technologies (6, 7).

In an effort to reduce treatment time and increase effectiveness, new methods have been introduced to accelerate orthodontic tooth movement. Four non-invasive techniques, that are used to accelerate orthodontic movements, are described in the literature: application of electric currents (8) or electromagnetic fields (9), LLLT (10, 11, 12) and mechanical vibration application. Studies have shown that cellular response may be modified by application of mechanical forces and this response may be controlled using these non-invasive devices during the treatment period.

Intrusive application of these techniques can lead to unwanted and very harmful side effects. For instance, early signs of orthodontic overload are manifested in the vascularization of the dental pulp and the marginal gingiva, which can be assessed objectively by using a Laser Doppler Flowmetry (LDF) with a proper technique (13, 14, 15, 16). LDF is a non-invasive diagnostic tool that allows the early, objective, continuous and real-time evaluation of the vascular dynamics in the dental pulp (17, 18, 19, 20) and marginal periodontium (21, 22, 23).

Low-Level Laser Therapy (LLLT) has been shown to have biological effects on hard and soft tissues in dentistry. LLLT stimulates bone remodeling by induction of osteoblasts proliferation in the tension site and osteoclasts in the pressure site (24).

As another non-invasive method vibrational stimulus, used as a method to increase the rate of bone remodeling have been shown as a promising and convenient solution.

In this overview the earlier mentioned techniques will be discussed in order to better understand their work mechanisms and their effectiveness during orthodontic treatment.

MATERIAL AND METHODS

An electronic search for relevant articles regarding accelerated orthodontic tooth movements was conducted using *Medline-PubMed, ScienceDirect, Springer Link* and *Web of Science* via *e-information.ro* electronic platform. From the studied literature, the articles that mentioned LLLT and vibrational devices that may accelerate tooth movement and shorten the orthodontic treatment period were selected.

Low Level Laser Therapy

Low-Level Laser Therapy (LLLT) or photo biomodulation is successfully applied to orthodontics and is known as Light Accelerated Orthodontics (LAO) (25). In the specialty literature are mentioned multiple effects of the light radiation in the tissues such as stimulation of the dentoalveolar complex with a potential impact on ATP production by mitochondrial cells. During the tooth movement phase, higher ATP availability helps cells 'turnover' more efficiently leading to an increased remodeling process due to an elevated metabolic activity and accelerated tooth movement. Moreover, LLLT could increase vascular activity, which would also contribute to the rapid turnover of the bone and is amenable to light.

Many researches support the claim of increased osteoblastic activity following LLLT *in vivo* (26) and *in vitro* (27, 28). On the other hand, recent studies have indicated enhanced osteoclastic activity after Low-Level Laser Therapy *in vivo* and *in vitro* (29).

A number of clinical studies (30, 31, 32,

33) have suggested that LAO may also lead to increased velocity of canine movement and decreased pain, and a significantly higher acceleration of retraction of treated canines. In addition, LLLT stimulates vascularization, epithelization and collagen synthesis (34) and has an analgesic, biomodulatory and anti-inflammatory effect on dental tissues (35, 36, 37) that may influence the outcome of orthodontic treatment.

Vibrational devices

Cyclic vibration (38) also known as low-level oscillatory signals application Low Intensity Pulsed Ultrasound (LIPUS) (39), Low-Intensity Vibration (LIV) (40, 41) or Low-Frequency Mechanical Vibration (LFMV) (42) can have various positive effects. There is compelling evidence that bone remodeling can be significantly accelerated through the application of pulsating force of various frequency and magnitude (43) and also depends on general health status (44).

Studies support the idea of two main theories that explain the bone remodeling process: piezoelectricity generated in the alveolar bone and pressure-tension sites within the periodontal ligaments. (45). Mechanical forces have a great influence on bone remodeling, mechanical cyclical stretching, fluid shear stress, compression, and microgravity play different roles in cell differentiation and proliferation by affecting intracellular interactions (46).

It has been shown that cyclic forces transmitted multiple times to biological structures lead to a faster response at cellular level (43). Clinical studies have shown that factors increasing the rate of bone remodeling also increase the rate of tooth movement (10, 11).

DISCUSSION

Low-Level Laser Therapy or **photo biomodulation** is a non-invasive technique which uses specific wavelength range, intensity and light penetration.

We emphasize that the impact of the LLLT on the tissues will be dependent on the wavelength and light intensity and other specific working parameters of laser radiation.

According with Elkatan *et al.* (47) acceleration of orthodontic tooth movement using LLLT is dose-dependent, very low dose or very high dose will not cause acceleration**.** LLLT with the optimum dose can be used during retention to decrease the retention period, but a retainer should be used. Otherwise the relapse tendency would increase.

Fromont-Colson *et al.* (12) stated that LLLT can be effective for accelerating orthodontic movement but it may be necessary to concentrate research efforts on finding the optimal dose for LLLT.

Kau *et al.* (25), had determined that LAO leads to increase in the rate of orthodontic tooth movement and also demonstrate its efficacy in humans in a large cohort. An important observation to note is that the impact of LAO was independent of the center and investigator effect, which makes it even more viable in clinical settings in general practice.

It is well known that LLLT has a biostimulation effect on cell proliferation and wound healing (10) and also could be used on soft tissues as a photodynamic therapy (48). In certain, *in vivo* animal and human experiments LLLT enhanced the velocity of orthodontic tooth movement and improved the quality of bone remodeling (4, 10, 11).

Several clinical trials based on animal models and human subjects have investigated the effect of LLLT on accelerating orthodontic tooth movement (47, 49, 50).

Also reviews conducted on the subject suggested that LLLT may be effective but given the limited amount of information

available and relatively small number of studies further investigation may be required (12, 51).

Ge M.K. *et al.* (52) throughout their research concluded that LLLT might accelerate orthodontic tooth movement and they found that there is no adverse effect associated to this treatment. Also, they related that relatively low energy densities (2.5, 5, 8 J/cm^2) were more effective, however an optimal dose remained yet undetermined.

Samara S.A. *et al.* (53) found that photo biomodulation therapy applied for 3 min/ day accelerates orthodontic space closure, however in their opinion to establish a standardized protocol further clinical studies are needed.

Sedky Y. (54) *et al.* concluded that both low-level laser therapy and cortectomy-facilitated orthodontics can reduce the treatment period, but LLLT has the advantage of being non-invasive.

In the study conducted by Yassaei S. *et al.* (55), applying a 980 nm diode laser would not significantly increase the rate of orthodontic tooth movements, although changes at cellular level were noticeable.

The limited number of clinical studies, different protocols and potential publication bias is the reason that LLLT effectiveness may be questioned, idea sustained by Long H. *et al.* (51) in their meta-analysis and by Sonesson M. *et al.* (56) in their systematic review.

The results of our literature search regarding LLLT was summarized in tab. I.

TABLE I.

Literature search for LLLT articles

No.	Author names and year	Study Type	Results
1.	Elkattan A.E. *et al.*, 2012	Clinical study	Increases the rate of orthodontic tooth movement
2.	Isola G. *et al.*, 2019	Clinical study	Increases the rate of orthodontic tooth movement
3.	Alazzawi M. *et al.*, 2018	Clinical study	Increases the rate of orthodontic tooth movement.
4.	Fromont-Colson C. *et al.*, 2017	Review	Can be effective. Further investigation is necessary.
5.	Ge M.K. *et al.*, 2015	Meta-analysis	Effective in accelerating the rate of orthodontic tooth movement.
6.	Ghizlane G. *et al.*, 2013	Clinical study	Increases the rate of orthodontic tooth movement.
7.	Mohammed M. *et al.*, 2014	Review	May increase the rate of tooth movement, useful tool in clinical orthodontics.
8.	Kau C. *et al.*, 2013	Clinical study	Increases the rate of orthodontic tooth movement.
9.	Sachin K. *et al.*, 2019	Review	Increase in bone density, as well as increased expression of osteogenesis markers.
10.	Samara S.A. *et al.*, 2018	Clinical study	Effective in orthodontic active space closure.
11.	Sedky Y. *et al.*, 2019	Clinical study	Increases the rate of orthodontic tooth movement and has the advantage of being non-invasive compared to cortectomy-facilitated orthodontics
12.	Long H. *et al.*, 2015	Meta-analysis	Weak evidence, although may accelerate orthodontic tooth movement. Insufficient data, more studies are needed.
13.	Sonesson M. *et al.*, 2017	Review	Low quality of evidence, need for consistency in study design and conformity of laser method.
14.	Üretürk S.E. *et al.*, 2017	Clinical study	Increases the rate of orthodontic tooth movement.
15.	Yassaei S. *et al.*, 2016	Clinical study	No significant changes in the rate of orthodontic tooth movement.

Low-level mechanical oscillatory signals (vibrations) have been proved to increase the rate of bone remodeling (38).

Goyal V. *et al.* (43) in their review concluded that mechanical vibrations have positive effect on the bone architecture and promote osteogenic activity.

We accentuate that the effectiveness of vibrational devices to accelerate the rate of orthodontic tooth movement is influenced by vibration parameters. The results will mainly be dependent on duration of use and the frequency of the cyclic loading.

In recent years, several clinical studies have investigated the effects of vibrations on the rate of orthodontic tooth movement (38, 57, 58, 59).

Pavlin D. *et al.* (38) in their clinical trial have found that applying cyclic loading (vibrations) of 0.25 N at a frequency of 30 Hz in association with a fixed orthodontic appliance will significantly accelerate the rate of orthodontic tooth movement.

Jing D. *et al.* (60) have presented in their review that there is a need for well-designed high-quality clinical trials in order to obtain reliable results. They have also concluded that vibrational stimulus is effective for accelerating tooth movement in canine retraction but not in the alignment phase.

Lobre W. *et al.* (1) used vibrational devices to lower the pain perception that is associated with the use of fixed orthodontic appliances. During the 4-month test period the micro pulsed vibration device group felt significantly more comfortable compared to the control group. These findings are challenged by Miles P. *et al.* (45) clinical trial results, where the vibrational devices had no effect on pain alleviation.

Orton-Gibbs *et al.* (58) demonstrate that the use of vibrational devices in an orthodontic practice can significantly reduce treatment time, but they also consider that further testing is necessary. These findings correspond with Bowman S.J. *et al.* (57) results, where a 30% increase in the rate of tooth movement during orthodontic levelling phase was noticeable.

Given that root resorption is a potential side effect of any orthodontic treatment, the effects of these devices had to be evaluated. There is no clear evidence that using a vibrational device as an adjuvant during treatment may cause root resorption. Chung H.K. (61) after radiological evaluation, found that there is no significant difference after using these devices and states that further testing and a longer follow-up period is needed.

The results of the literature search conducted on vibrational devices applied in orthodontics was introduced in table II.

TABLE II

Literature search for articles about vibrational devices

No.	Author names and year	Study Type	Results
1.	Pavlin D. *et al.*, 2015	Clinical study	Increases the rate of orthodontic tooth movement.
2.	Lobre W. *et al.*, 2016	Clinical study	Reduces the perception of pain. Further studies are needed.
3.	Orton-Gibbs S. et al., 2015	Clinical study	Effective in accelerating the rate of orthodontic tooth movement.
4.	Jing D. *et al.*, 2017	Review	Increases the rate of orthodontic tooth movement. There is a need for well-designed clinical trials in order to obtain more reliable information.
5.	Bowman S.J. *et al.*, 2015	Clinical study	Increases the rate of orthodontic tooth movement.
6.	Miles P. *et al.*, 2012	Clinical study	No advantage for the early resolution of crowding or the alleviation of pain during orthodontic treatment.
7.	Goyal V. *et al.*, 2018	Review	Increases the rate of orthodontic tooth movement.
8.	Chung H.K., 2011	Clinical study	There is no clear evidence that using a vibrational device may cause root resorption.

CONCLUSIONS

From the articles about LLLT that were included in our study 12 out of 15 stated that its use increases the rate of orthodontic tooth movement and 3 out of 14 concluded that there is no, or weak evidence that it would reduce treatment time. From the studies conducted on vibrational devices, that we analyzed, 7 out of 8 confirmed that its use during orthodontic treatment has positive effects and only one study described the device as having no effect.

Given the limitations of our overview, it can be concluded that LLLT and vibrational devices can be a genuine way to reduce classic orthodontic treatment duration and they have close to no side-effects. However, larger and longer clinical trials are required to assess the long-term stability of the treatment outcomes as well as the biological mechanisms in order to determine future clinical guidelines so that these devices could be routinely applied.

POSITIVE EFFECTS OF NATURAL SUBSTANCES IN CHEMOTHERAPY-INDUCED TOXICITY – A STUDY ON MICE

A recent study conducted on mice, shows the positive effects of the combination of chemotherapy with natural products. three such natural products, 1,8-cineols - terpenes present in many aromatic plants such as *Artemisia herba alba*, eucalyptus, sage, rosemary, and cardamom, *Exopolysaccharide* (EPS - an extracellular polysaccharides isolated from marine microorganisms by microbial fermentation, and Ellagic Acid (EA) - a natural phenol, which is found in various vegetables and fruits, have a positive effect on chemotherapy-induced toxicity. Supplementary substance-based studies on the human subjects are required to fully demonstrate the positive outcome of the combination. (Abdallah HMI, Abdel-Rahman RF, El Awdan SA, Allam RM, El-Mosallamy AEMK, Selim MS, Mohamed SS, Arbid MS, Farrag ARH. Protective effect of some natural products against chemotherapy-induced toxicity in rats. *Heliyon* 2019; 5(5): e01590).

CLINIC AND EVOLUTIVE ASPECTS OF CHILDREN TUBERCULOUS MENINGITIS (Abstract) : The aim of the study was to investigate the particularities of the clinical manifestation and evolution of tuberculous meningitis at children. **Material and method** : The study was made between January 2000 and December 2008 in Clinic of Infectious Diseases Iaşi and Emergency County Hospital „Sf. Ioan cel Nou" Suceava on a group of 169 children with tuberculous meningitis. **Results** : The majority (78.1%) of patients had poor socio-economic conditions and 22.4$ had a family TB contact. The onset of the symptoms was atypical in infants and small children with fever associated with digestive, neurological or pulmonary manifestations. The admission in hospital was delayed in 56.8% of patients and 39.05% had a severe general status with coma. The positive diagnosis was based on cytological and biochemical features of CSF, results of QuantilFERON. TB Gold, pulmonary images, family TB contact and evolution under anti-tuberculous therapy. We observed a high rate of complications represented by hydrocephaly (28.9%). 18 patients died (4 infants), the cause of dead being meningeal coma or complications. **Conclusion** : The diagnosis of tuberculous meningitis at children remains a problem because of the atypical clinical manifestation, the delay of initiating the therapy causing high mortality and frequent complications. **Key words** : CLINICAL TUBERCULOSIS, MENINGITIS, CHILDREN

Tuberculoza este una din problemele majore de sănătate populaţională la nivel mondial. În România sunt raportate, anual peste 30.000 de cazuri noi sau recidive, cu dezvoltarea unor forme grave de boală la copilul mic şi sugar (1, 2). Concomitent cu tuberculoza pulmonară, o recrudescenţă deosebită o au în prezent şi formele extrapulmonare, printre care şi meningita tuberculoasă (2, 3).

Studiul nostru a urmărit evidenţierea particularităţilor clinice şi evolutive ale meningitei tuberculoase la copil, într-o zonă din nord-estul României.

MATERIAL ŞI METODE

În studiu au fost incluse 169 de cazuri de meningită tuberculoasă la copil, internate în Clinica de Boli Infecţioase Iaşi şi Spitalul Judeţean de Urgenţă „Sf. Ioan cel Nou", Suceava, în perioada 2000-2008. Au fost analizate, retroprospectiv, datele demografice (vârsta, sexul, mediul de provenienţă), factorii favorizanţi, manifestările clinice, importanţa examenelor paraclinice, evoluţia clinică şi programele terapeutice.

REZULTATE

1. Date demografice. Incidenţa anuală a

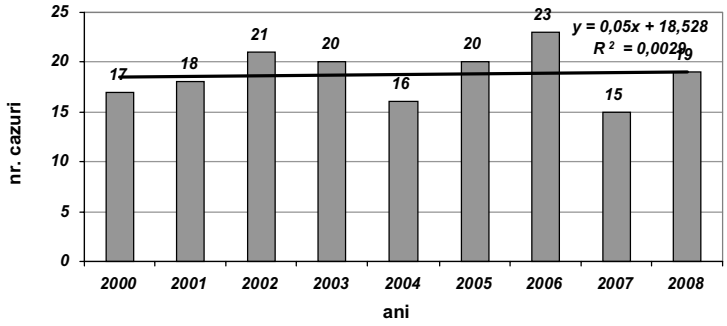

Fig. 1. Incidenţa anuală a meningitei TB la copil

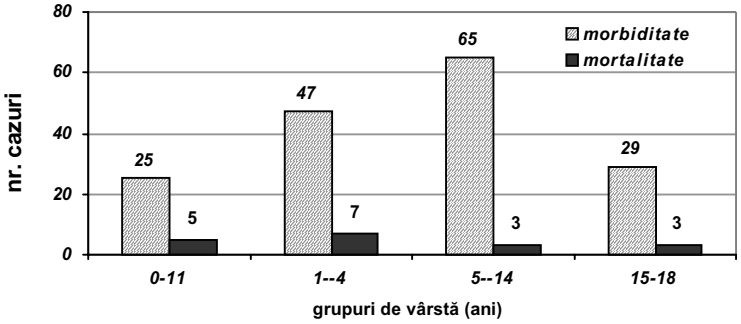

Fig. 2. Distribuţia cazurilor de meningită TB pe grupuri de vârstă

cazurilor de meningită tuberculoasă (TB) în lotul studiat a fost influenţată de evoluţia epidemiei de tuberculoză cu valori ridicate, cu maximum în anul 2006, când s-au înregistrat 23 cazuri (13,6%) (fig. 1).

Repartiţia cazurilor pe grupuri de vârstă a evidenţiat o incidenţă maximă la grupul 5-14 ani (40,23%), urmată de 1-4 ani (27,81%) (fig. 2).

Incidenţa pe sex nu a indicat diferenţe semnificative ($p \geq 0,05$), fiind de M/F = 89/80, cu uşoară predominanţă a sexului masculin. Diferenţa pe medii a fost semnificativă ($p \leq 0,05$) înafara mediului rural (U/R = 21,8/78,1%). Nu s-a remarcat nici o diferenţă sezonieră.

2. Factori favorizanţi (exceptând infecţia HIV/SIDA), în apariţia meningitei TB, au fost astfel: condiţii socio-economice precare (78,1%); focar familial (22,48%); TB pulmonară netratată (4,73%); afecţiuni patologice preexistente care au condus la scăderea imunităţii (11,24%) (2,3).

3. Diagnosticul clinic al meningitei tuberculoase. Prodromul a fost frecvent insidios, cu durata între 1 şi 4 săptămâni marcat de scăderea apetitului (88%); agitaţie (72%); iritabilitate (68%); reducerea interesului pentru joacă (78%); senzaţie de greaţă şi vărsături (65%); dureri abdominal difuze (36%); febră rebelă la terapia cu antibiotic (18,3%). Simptomele de debut au fost polimorfe, atipice la sugar şi copilul mic, spre deosebire de şcolar la care s-a manifestat frecvent un tablou clinic sugestiv pentru meningită: febră + sindrom meningeal/sindrom encefalic (83,4%); febră + sindrom pseudotumoral (1,2%); sindrom febril prelungit peste 14 zile (5,3%); febră + tulburări gastrointestinal (8,9%); febră + imagine pulmonară de tip pneumonic persistent sub antibiotic (1,2%) (4,5,6).

Polimorfismul simptomelor de debut a stat la baza internării tardive pentru un număr de 96 (56,8%) cazuri (tab. I). Starea general la internare a fost gravă (39%) pa-

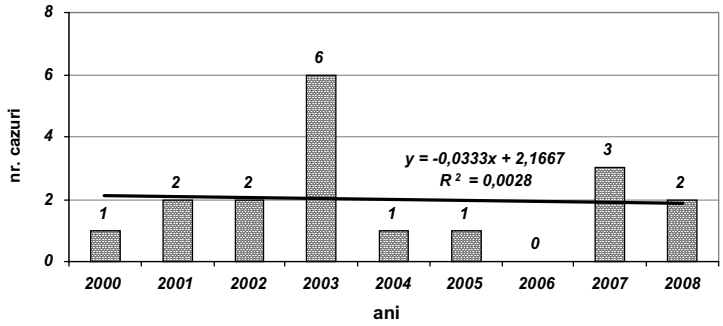

Fig. 3. Mortalitatea anuală prin meningita TB la copil

TABELUL I

Momentul internării în relaţie cu debutul bolii

	Intervalul: debut/internare (zile)			
	1-7	*8-14*	*15-21*	*>21*
Nr. cazuri	73	63	18	15
%	43,2	37,2	10,7	8,9

TABELUL II

Modificarea stării generale la internare

	Modificarea stării generale la internare		
	Gravă	*Uşoară*	*Medie*
Nr. cazuri	66	80	23
%	39	47,3	13,7

cienţi, dintre care 18,9% erau în comă gr. III (Scor Glasgow 5-8) (tab. II).

În perioada de stare s-au semnalat manifestări digestive (vărsături, dureri abdominale, constipaţie) şi fenomene de suferinţă encefalitică, acestea din urmă fiind prezente la majoritatea pacienţilor, şi s-au evidenţiat prin: convulsii tonico-clonice localizate şi generalizate – 34,9%; coma gr. II/III – 33,6%; pe parcursul internării coma cu sfârşit letal s-a aprofundat (gr. IV) la 8,3% dintre pacienţi; bradipsihie, somnolenţă – 28,9%; sindrom confuzional – 13,6%; tulburări cognitive şi de limbaj – 2,9%; paralizii de nervi cranieni – 32,5%; hemipareză/ hemiplegie – 19,5%; parapareză – 2,3%. Manifestările respiratorii au fost reprezentate prin detresă respiratorie şi apnee în 16,5%, iar manifestările cardiac prin bradicardie în 7,7% din cazuri.

4. Diagnosticul pozitiv. Elemente orientative: noţiunea de contact familial de TB la 34,3% sau de TB pulmonară în antecedente; simptome clinice, care de multe ori au fost polimorfe şi atipice, însă persistente sub terapia cu antibiotice (9,5%), în special la sugar şi copilul preşcolar au dus la suspiciunea de meningită TB. *Elemente de certitudine*: afectarea pulmonară caracteristică pentru TB a fost prezentă la 53,8% şi a constat în forma miliară – 20,7%; pneumonie cu pleurezie – 2,9%; pneumonie lobară – 9,5%; TB ulcero-cazeoasă – 1,8%; TB nodular-infiltrativă – 10%; adenopatii hilare – 8,8%; absenţa leziunilor pulmonare nu a infirmat etiologia bacilară a meningitei; modificări citobiochimice particulare ale LCR la 60,9%; examenul direct al LCR, în coloraţia Ziehl-Nielsen, a fost negativ în toate cazurile; cultura LCR, pe mediul Lowenstein-Jensen, a evidenţiat prezenţa *Mycobacterium tuberculosis* la 27,8%; în două cazuri s-a izolat o tulpină de *M. tuberculosis* rezistentă la izoniazidă; testul QuantilFERON TB Gold pozitiv în sânge la 14,8% pacienţi şi pozitiv în LCR la 60% din cele 40 de cazuri de meningită TB testate; examenul CT cranio-cerebral a fost practicat la 66,2% pacienţi îndeosebi cei cu complicaţii sau probleme de diagnostic; au fost evidenţiate modificări patologice de tip: hidrocefalie – 43,7%; tuberculoame – 20,5%; edem cerebral – 13,6%; infarcte multiple – 4,46%; hemoragii subrahnoidiene

TABELUL III

Evaluări asupra prevalenţei sechelelor, pe un lot de 169 cazuri de meningită TB

Sechele	Nr. cazuri	%
Hidrocefalie fără sunt VP	25	14,8
Hidrocefalie cu sunt VP	24	14,2
Retard psihomotor	15	8,9
Pareze ale membrelor	12	7,1
Cecitate	8	4,7
Hipoacuzie	7	4,14
Atrofie corticală	6	3,5
Paralizii ale nervilor cranieni	5	2,95
Encefalopatie gravă	5	2,95
Epilepsie GM	3	1,8
Higroma	2	1,2

– 2,67% ; atrofie corticală difuză – 6,25% ; encefalită presupurativă – 2,67% ; şi arahnoidită bazală la 3,57% pacienţi (7,8,9).

5. Evoluţia meningitei TB a depins de precocitatea diagnosticării şi introducerii tratamentului. Copiii care au primit tratament anti – TB în primele 10 zile de boală au fost recuperaţi în 86,4% din cazuri iar cei care au beneficiat de un tratament instituit după 10 zile de boală, s-au recuperat doar în 23,4% cazuri.

Urmărind relaţia dintre momentul introducerii terapiei anti – TB şi ameliorarea stării clinice au fost luaţi în considerare următorii parametri : ieşirea din comă a fost posibilă la 68,42% pacienţi din 57, după 5 şi 21 zile ; remiterea paraliziilor de nervi cranieni s-a constatat în 90% din cazuri la un interval de 14 – 30 de zile ; ameliorarea fenomenelor de focalizare a fost evidentă în 69,3% din 33 cazuri, după 6 săptămâni de tratament ; sindromul meningean îndeosebi la preşcolari şi şcolari s-a remis într-un interval de 4 – 21 zile ; apirexia s-a instalat, în medie, după 12,3 zile ; durata medie a spitalizării a fost de 63,5 zile, cu un minimum de 24 ore şi maximum 168 zile.

6. *Complicaţiile* care au apărut în decursul bolii au fost reprezentate de : hidrocefalie (28,9%) ; tuberculoame cerebrale unice sau multiple (12,4%) ; hemipareze / hemiplegie (19,5%) ; parapareză (2,3%) ; arahnoidita optochiasmatică (2,3%) ; paralizii ale nervilor cranieni II, VI, VII (32,5%) ; hipoacuzia (1,5%) ; hepatopatia medicamentoasă indusă, probabil de rifampicină (12,4%). Sechelele postmeningită TB au fost îndeosebi, de tipul hidrocefaliei (28,9%) (10,11) (tab. III).

7. Mortalitatea prin meningita TB. Din cei 169 pacienţi cuprinşi în studiu au decedat 18 (10,6%), dintre care 22,2% în primele 3 zile de spitalizare ; sexul feminin fiind cel mai afectat (7,1%). Incidenţa deceselor a fost mai mare la copilul mic şi sugar, înregistrându-se 4,1% decese între 1-4 ani. Mortalitatea a fost în scădere în ultimii ani, cele mai multe decese la copii înregistrându-se în anul 2003 (fig. 3).

Factorii care au agravat evoluţia bolii favorizând decesul au fost reprezentaţi de spitalizarea tardivă şi starea generală gravă la internare (5,9%), decesul survenind la un interval de 2,4 – 4 zile de la instituirea terapiei. Celelalte 7 (4,1%) cazuri de deces s-au produs după 16-35 de zile de tratament prin complicaţii : ramolisment cerebral, hidrocefalie tetraventriculară şi edem cerebral refractar la tratament patogenic.

DISCUŢII

Studiul a avut drept scop evidenţierea particularităţilor meningitei TB la copil, care în perioada 2000 – 2008 a reprezentat peste 30% din totalul cazurilor de neuro – infecţii. Anual, s-au înregistrat între 15 şi 23 îmbolnăviri.

Între factorii favorizanţi ai îmbolnăvirilor s-au semnalat : condiţiile socio-economice precare la 78,1% şi existenţa focarelor familiale de TB la 22,4% pacienţi. La sugar şi copilul mic au predominat simptome de debut polimorf, care au cauzat temporizarea internării în Clinica de Boli Infecţioase, în 65,2% din cazuri.

Suferinţa encefalitică a avut o frecvenţă semnificativă în lotul studiat, având aspecte clinice variate de la convulsii, paralizii de nervi cranieni, somnolenţă până la comă encefalitică de gradul III. Procentul de 91,7%, raportat de noi este, mult superior celui constatat în alte ţări (4,5,6). Simptomatologia predominant neurologică depistată la 39,4% dintre cazurile studiate este similară cu cea raportată în alte studii (5, 6, 7).

Diagnosticul de certitudine al meningitei TB s-a obţinut prin izolarea bacilului Koch din LCR în 27,8% din cazuri (4,89%). Dintre complicaţiile meningitei TB cea mai frecventă a fost hidrocefalia tetra– sau triventriculară, prezentă în 49 (28,9%) cazuri (10,11). Evoluţia a fost favorabilă pentru 24 (14,2) bolnavi cărora li s-a aplicat shunt ventriculo-peritoneal.

CONCLUZII

Simptomele de debut al meningitei TB au fost polimorfe, mimând diferite afecţiuni, ce au determinat adresabilitatea cu întârziere la medicul infecţionist. Starea generală la internare a fost gravă în 66 (39%) cazuri.

Cea mai frecventă complicaţie a fost hidrocefalia constatată la 28,9% din cazuri. S-au înregistrat 18 (10,6%) decese, dintre care 4 (2,3% cazuri la sugar şi 9 (5,3%) la copilul 1-4 ani. Cauza directă a morţii a fost coma meningitică sau complicaţiile de tipul hidrocefaliei tetraventriculară şi ramolismentul cerebral. Factorii majori ai prognosticului nefast au fost reprezentaţi de vârsta mică, gravitatea bolii la internare şi momentul tardiv al internării.

NEW INSIGHTS INTO AORTITIS CLASSIFICATION: A MINIREVIEW **(**Abstract): Aortitis is a general term that refers to a broad category of infectious or noninfectious conditions in which an abnormal inflammation of the aortic wall occurs. These inflammatory conditions have different clinical and morphologic features and variable prognoses. The most common causes of noninfectious aortitis are the large vessel vasculitis, including giant cell arteritis and Takayasu arteritis, together with several rheumatic diseases. Infectious aortitis is a rare but potentially life-threatening disorder. In this paper, we reviewed the most common etiologic types of aortitis, noting some diagnostic issues, discussing some pathological classifications suggestive of a certain etiology and outlining the role of the pathologist. **Keywords**: AORTITIS, INFLAMMATION, VASCULITIS.

DEFINITION

Aortitis is an inflammatory process involving the aortic wall, regardless of the underlying cause. Most frequently the intima and media-intima junction, as well as the adventitia are involved. At the level of the media, the inflammatory infiltrate is associated with fragmentation of elastic fibers, smooth muscle cell (SMC) necrosis of various degrees and fibrosis (1).

AORTITIS ETIOLOGICAL CLASSIFICATION

Many criteria are used in aortitis classification. The most widely used classification of aortitis considers the etiology of the aortic inflammation (tab. I) (2).

In this classification, aortic wall inflammation may be either infectious or, more often, noninfectious. Noninfectious aortitis, a form of large-vessel vasculitis, can be grouped into: (a) giant cell aortitis, such as giant cell arteritis (GCA) and Takayasu arteritis (TA); (b) autoimmune aortitis, such as rheumatoid arthritis and ankylosing spondylitis; (c) idiopathic aortitis including inflammatory aortic aneurysm. Infectious aortitis may be secondary to fungal infection, tuberculosis, syphilis or infections with *Salmonella* or other bacterial agents.

CLINICAL MANIFESTATIONS AND DIAGNOSTIC APPROACH

There are various clinical presentations, including, for instance, hypertension in young patients suffering from TA; back or abdominal pain accompanying a thoracic or abdominal aortic aneurysm; vasculitis -

induces systemic inflammatory syndrome; aortic thrombosis with distal embolization; aortic dissection or rupture, etc. The recommended laboratory investigations are complete blood count, kidney and liver function tests, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), blood cultures, rheumatologic panel (antibodies to nuclear antigen-ANA, antineutrophil cytoplasmic antibodies - ANCA, rheumatoid factor - RF), skin test for tuberculosis, serological test for syphilis, etc. (3). Imaging is also useful for monitoring disease activity and guided biopsy in selected cases (e.g., in TA). Commonly, conventional angiography is the initial imaging study performed. Multidetector computed tomography (CT) helps with evaluating both arterial wall changes and abnormalities of the aortic lumen, whereas magnetic resonance imaging (MRI) is recommended for serial imaging in patient follow-up (4).

TABLE I
Etiologic classification of aortitis

1. Noninfectious	**2. Infectious**
○ Giant cell aortitis ○ Takayasu aortitis ○ Aortitis associated with autoimmune diseases • Rheumatoid arthritis • Ankylosing spondylitis • Behçet disease • Systemic lupus erythematous • Reiter syndrome • SystemicIgG4-related autoimmune disease ○ Lymphoplasmacytic aortitis	○ Bacterial • Salmonella • Staphylococcus species • *Streptococcus Pneumoniae* ○ Luetic (*Treponema pallidum*) ○ Mycobacterial (*Mycobacterium tuberculosis*) ○ Fungal
	3. Idiopathic aortic inflammatory aneurysm

The most widely used etiological classification, distinguishing between noninfectious and infectious causes, offers the advantage of better guiding the therapy of these disorders.

1. Non-Infectious Aortitis

GCA is a chronic granulomatous vasculitis that affects large and medium-sized vessels and usually the superficial cranial arteries are involved. Aortic injury occurs in 10-15% of GCA patients. The disease incidence increases with age (beyond the age of 50 years) and is also higher in women (two-fold to four-fold) (5). Aortic involvement usually manifests as aortic valve insufficiency and ascending aortic aneurysm in about 10% of aortitis (2). Aortic dissection rarely occurs (6).

GCA pathogenesis is secondary to a systemic granulomatous vasculitis and is closely related to polymyalgia rheumatica. Vascular inflammation may be widespread, most commonly involving the superior temporal artery, as well as the aorta and its branches (4, 5).

Histologically, the acute stage is characterized by inflammatory cellular infiltrate with multinucleated giant cells, lymphocytes, plasma cells and macrophages in the areas of destruction and lamellar fragmentation, while in the chronic stage there is progressive fibrosis of the vessel wall. Intimal fibrosis is present but not to a similar extent as in TA (5).

TA, also known as aortic arch syndrome, pulse less disease, or occlusive thromboaortopathy, is a necrotizing and obliterative segmental, large-vessel panar-

teritis of unknown cause. It is more common in young females (aged less than 50 years) and it is thought to be secondary to an autoimmune process. TA is associated with mycobacterial infection (tuberculosis) and with rheumatoid arthritis. Histology reveals degeneration of the media with a dense inflammatory infiltrate, including giant cells; there is a marked infiltration of mononuclear cells in the adventitia with perivascular cuffing of the vasa vasorum in the early stage, followed by fibrosis and calcification in the late stage, leading to occlusion and narrowing of the aorta and its branches (7).

TA is generally divided into two clinical stages. In the early stage, known as the systemic or prepulseless phase, clinical manifestations are mainly vague making diagnosis difficult during this interval. In the late stage, known as the occlusive or pulseless phase, aortic and branch vessel disease may manifest itself as stenosis or luminal narrowing or, less frequently, as aneurysmal dilatation that ensues after inflammation and destroys the media (8, 9).

In contrast to GCA, TA is more often associated with extensive intimal and adventitial fibrosis or scarring with resultant luminal narrowing. At the same time, in GCA "skip lesions" are more regular (10). Often, aortic wall thickness is greater among patients with TA than GCA.

Rheumatoid aortitis. Aortitis in rheumatoid arthritis (RA) is rare and less common than myocardial or valvular involvement. Aneurysms may occur in the thoracic or abdominal aorta, may rupture or cause aortic insufficiency. Histologically, inflammation consists of lymphocytes, plasma cells and macrophages, with or without the presence of rheumatoid nodules. Typical inflammation affects media and adventitia. In the destroyed media, SMCs and elastic lamellae are replaced by collagen fibers (11).

Ankylosing Spondylitis. Aortic root and aortic valve are the most commonly involved areas in patients with ankylosing spondylitis. In aortitis-dependent aneurysm formation, the aortic wall changes are common in affected patients, and aortic valve thickening is associated with valvular insufficiency (12).

Beçhet's Disease is an idiopathic vascular inflammatory disease characterized by mucocutaneous ulcers. Rarely, multiple aneurysms develop in large vessels such as the aorta. In the active stage of aortitis, there is a chronic inflammatory medial and adventitial infiltration with formation of a cuff around vasa vasorum with rare giant cells, while in the late stage there is fibrous thickening of the media and adventitia with endarteritis obliterans (13).

Systemic lupus erythematous. The aortic aneurysm is a rare complication in lupus erythematosus with involvement of ascending aorta that requires surgical aortic replacement (2, 14, 15).

Lymphoplasmacytic aortitis is characterized by a diffuse or multifocal medial inflammatory infiltrate consisting of lymphocytes and plasma cells, along with medial necrosis. As an autoimmune disease, it is characterized by the presence of IgG4-secreting plasma cells, hence the name of systemic IgG4-related autoimmune disease (16, 17).

2. Infectious Aortitis

Infectious aortitis is an inflammatory process within the aortic wall induced by microorganisms. Commonly, it is a complication of bacterial endocarditis secondary to *Streptococcus pyogenes*, *Streptococcus pneumoniae*, and *Staphylococcus*. Occasionally, specific infectious agents are involved, such as *Mycobacterium tubercu-*

losis, *Treponema pallidum*, and others (2).

Pyogenic aortitis was originally described and named "mycotic aneurysm" by Osler in 1885. The term of infected aneurysm is now preferred to mycotic aneurysm for avoiding confusion with fungal infection. The possible invasion route could be implantation on the intimal surface spread of infection through the vasa vasorum, direct extension from a contiguous extravascular focus, or traumatic inoculation of contaminated material. Histologically, it is characterized by medial destruction with the formation of micro abscesses. Morphologically, these aneurysms are mostly saccular rather than fusiform. The microbial agents generally involved are salmonella, streptococci, staphylococci and gonococci (1, 18).

Syphilitic aortitis. Syphilis is a sexually transmitted chronic systemic infection produced by the *Treponema pallidum* spirochetes. The clinical findings depend on the duration of infection and are divided into three stages: primary, secondary, and tertiary. Cardiovascular manifestations specific to tertiary syphilis are usually evident 5-30 years after the primary infection and are secondary to endarteritis obliterans of the vasa vasorum. Commonly, luetic aortitis involves the ascending thoracic aorta. Grossly, the intimal "tree bark" appearance is the result of the proximal aorta involvement. In the late stages, these characteristic lesion**s** may be masked by atherosclerotic (ATS) injuries. Histologically, there are perivascular lymphocytes and plasma cells around vasa vasorum affected by endarteritis obliterans. Inflammation spreads within the media, where it determines acute necrosis of the aortic wall with neutrophilic infiltration (microgome) which may contain treponemes, as demonstrated with Warthin-Starry staining (19, 20).

Tuberculous aortitis involves the thoracic and abdominal aorta with equal frequency. It occurs in patients with latent tuberculosis (TB) due to direct extension from contiguous mediastinal lymph nodes or by hematogenous or lymphatic spread. Pathologic samples display TB granulomas (caseous necrosis, multinucleated giant cells and epithelioid cells) in the adventitia and media. Complications include wall rupture or aneurysm formation (21, 22).

3. Idiopathic aortitis is typically asymptomatic and is diagnosed only by the pathologist after surgery for aortic aneurysms, because some patients with this form of idiopathic thoracic aortitis develop an aortic aneurysm also known as idiopathic inflammatory aortic aneurysm.

There are several hypotheses explaining this idiopathic aortic disease: immune response to various components of aortic fibro atheromatous plaques; viral infection (Herpes simplex virus, cytomegalovirus, Epstein Barr virus); periadventitial fibrosis secondary to focal wall ischemia; aortic localization of systemic vasculitis; primary autoimmune disease (23, 24).

A term often used as a synonym for this type of aortic inflammatory disease is "chronic peri aortitis" (CPA), which actually refers to a group of diseases, including retroperitoneal idiopathic fibrosis and perianeurysmal retroperitoneal fibrosis as well as inflammatory aneurysm of abdominal and possibly thoracic aorta, sharing the findings of marked periadventitial inflammatory infiltrate and fibrosis. The histopathological approach is based on the coexistence of intimal complicated fibro atheromatous plaques, significant adventitial inflammatory infiltrate with lymphoid follicles and germinal centers and periadventitial fibrosis (25).

Pathological classifications

In 2008, Burke *et al*. have proposed a strictly histological classification of aortitis considering the distinction between necrotizing and non-necrotizing forms, whereas the examining pathologists completely ignore the clinical findings (3). Considering the histological data analysis regarding the presence or absence of medial necrosis, the authors concluded that histology correlates with etiology: GCA is associated with non-necrotizing aortitis, while TA and other autoimmune diseases are more frequently associated with necrotizing aortitis.

Another pathological subclassification derives from the pattern of the inflammatory infiltrate that suggests possible etiologies, such as: (1) granulomatous/giant cell pattern with or without compact/well-formed granulomas (GCA, TA, and RA); (2) lymphoplasmacytic pattern (IgG4-RD, syphilitic aortitis); (3) mixed inflammatory pattern (Behçet's disease); and (4) suppurative pattern (Staphylococcus, Streptococcus, Salmonella, Pseudomonas, and fungal infections) (26).

According to Stone *et al*. (26) the subclassification of aortitis often requires a combination of clinical, radiologic, laboratory, and pathologic information, because there are different gray areas, including the existence of overlapping lesions (some forms of aortitis and inflammatory aneurysm) in the context of a varied etiopathogenetic, pathological and clinical-evolutive spectrum.

Thus, in the near future, a detailed diagnostic approach could equally provide useful elements for the identification of new therapeutic targets and methods, including newer biologic treatments such as target specific anti-inflammatory molecules (27, 28).

Recent acquisitions on aortic pathology, in the light of the complexity of histopathological, biomolecular and pathophysiological substrates, should result in diagnostic and therapeutic reconsideration of aortitis, with the widening of the "systemic" evaluation by improving clinical study efficiency and enriching trials with imaging techniques, tissue histopathology, biomolecular and genetic analysis.

CONCLUSIONS

So, in the future, more studies will be needed with larger numbers of patients and applying multifield researches including novel tissue marker identification. In the working team, the pathologist responsible for the pathology report is meant to guide clinical screening for previously unsuspected autoimmune disease, and suggest the etiology of the inflammatory process, as well. The pathologist should also provide information about the degree of activity of the inflammatory process, which can be useful in predicting possible aneurysm recurrence.

MORPHOLOGICAL FEATURES OF ROMANIAN ENDEMIC *TEUCRIUM* L. SPECIES (Abstract): *Teucrium* is a genus that belongs to *Lamiaceae* family, but the endemic plants from our country have not been studied before. Therefore, **the aim** of this study was to provide evidence and specific characteristics with taxonomic value. **Material and methods**: we collected the plants (*Teucrium chamaedrys* L., *T. montanum* L. and *T. polium* L.) from the wild flora in the Northern Romania and we prepared section and microscopic plates from various organs (stems, branches, leaves and bracts). **Results:** the observed features were both common and different (quantitatively and qualitatively) between the species. **Conclusions:** we obtained for each species several specific characteristics that allow the proper identification even when the environmental conditions are not optimal for the complete growth of the plants. **Keywords**: TEUCRIUM, MORPHOLOGY, STEMS, LEAVES, TAXONOMY

Most species of *Lamiaceae* are medicinal plants long used in folk medicine known and appreciated for their active principles (α-pinene, β-pinene, limonene and menthol isolated from volatile oils and diterpenes, flavonoids and iridoids isolated from polar fractions) (1). The Romanian flora comprises about 33 genera and 130 species and subspecies of the *Lamiaceae* family (2). At present, this is one of the most famous and studied families of plants, the available data is abundant in chemical composition with important biological actions, in the most diverse fields: medicine, gastronomy, cosmetology (1, 3, 4, 5).

Volatile oils are recognized for their powerful anti-antioxidant and antimicrobial properties, while polar compounds such as flavonoids, iridoids and diterpenes exert important anti-inflammatory, antioxidant, anticancer and gastroprotective action. All the justified aspects are the remedies for using such species not only in traditional and modern medicine but also in daily life, in the form of nutritious teas, spices or flavorings (6, 7, 8).

The genus *Teucrium* has a wide distribution in Europe, Asia, America, Australia

and especially in the Mediterranean area, the latter comprising approximately 96% of the species. In Romania, the genus *Teucrium* comprises 5 species and several subspecies that grow in spontaneous flora. Plants are usually perennial, in the form of shrubs or sub-shrubs (2, 9, 10). The representatives of this genus are appreciated for their medicinal properties, both in modern medicine, proof being the numerous studies performed in the last 40 years, but especially in traditional medicine. It seems that the first information on the beneficial actions of these species was recorded by a Trojan king, Teucrion, after which the plants were also named, and dates back to our era. In traditional medicine, *Teucrium* species have been used for hundreds of years for their antioxidant, tonic, diaphoretic, analgesic, antipyretic, antirheumatic, antiseptic and hypoglycemic (1, 4, 5). Recently, cytotoxic and anticancer action has also been discovered (6). The remedies obtained from the aerial parts are rich in aromatic compounds with a bitter taste, so that they can be used as flavorings or in the form of spices, with a beneficial effect on the digestive system.

Although the anatomical structure of the *Lamiaceae* species has been studied extensively in the 19th and 20th centuries, in works referring only to medicinal plants, the species of *Teucrium* are rarely mentioned; only Cole (1992), referring to the significance of terpenoids, deals extensively with species of this genus. Nevertheless, only exotic taxa from the *Teucrium* genus are cited in the available literature.

Therefore, the aim of our research was represented by the description of three species of *Teucrium* endemic in Romania (9, 10), trying to find several features of taxonomic importance that would allow the proper identification of these species.

MATERIAL AND METHODS

Plant material

For our study we selected three Romanian endemic species as follows: *Teucrium chamaedrys* L., *T. montanum* L. and *T. polium* L. The chosen species were very little anatomically researched, which is why we also addressed this aspect in our research. The plants were harvested from the spontaneous flora, of Horlesti (*Teucrium chamaedrys* L. and *T. polium*) and Bicaz (*T. montanum* L.), during 20th and 30th of June 2019.

Preparation of the microscopic plates

The fresh vegetative organs (leaf and stems - the main axis and a lateral branch), were fixed in 70% ethyl alcohol. Prior to analysis, each sample was cross-sectioned through and the sections were colored using the double staining method, with ruthenium red and iodine green (12, 13, 14). The permanent preparations were made in glycerol gelatin and evaluated using the Euromex microscope (iScope series with 4x10, 10x10, 20x10, 40x10 lens) and Image Focus Alpha software. Euromex sCMEX- 20 was used for photography of each sample.

RESULTS AND DISCUSSION

The morphological characteristics observed in our study revealed both common and uncommon elements, especially for *T. montanum* as compared to the other two species.

Stem shape and anatomy

The cross-section of the stem is round and somewhat similar for *T. montanum* and *T polium*. For both samples, the pericycle is made of bundles of sclerenchymatous and parenchyma cells. However, the stem from

T. chamaedrys is square, with the ribs slightly protruding (fig. 1).

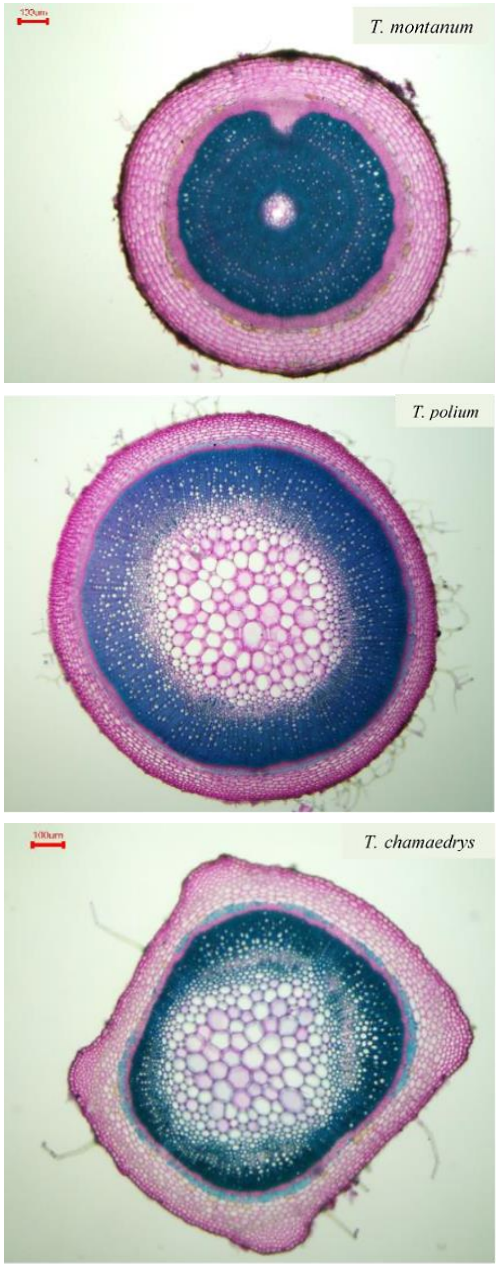

Fig. 1. Cross-sections through the stem of the investigated samples

Also, the bark of *T. montanum* is thicker (8 layers of cells) than the other two species and presents a thin collenchyma layer outward. The innermost layer of the cortex is primary endoderm, with cells strongly flattened radially and elongated tangentially. In the lateral walls, Caspary thickenings are also visible.

The epidermis of *T. montanum* is substantially exfoliated, which is why at the surface of the stem there are few trichomes, located only in the portions where this primary protective tissue persists. On the other hand, the epidermis of *Teucrium chamaedrys* has isodiametric cells of different size, with thicker internal and external walls, the latter being covered by a thin cuticle; just near the ribs the cuticle is very thick, the cutinization affecting all the thickness of the external wall. From place to place there are visible stomata, which project slightly above the epidermis. At the level of the epidermis, long, multicellular, uniseriate hairs are located, sometimes with arched tip and very short, pluricellular secretory beads (peltate hairs). Regarding the epidermis of *T. polium* contains isodiametric cells, with the outer wall thicker than the others and covered by the cuticle. Also, there are numerous multicellular trichomes, with the terminal cell much longer than the others and sometimes with a curved tip. The secretory trichomes are rare also multicellular, with a relatively short pedicel and a single or quadruple cell gland. Such elements have been previously noted in various *Teucrium* species from Serbia and Montenegro. Therefore, our results are in accordance with literature data (1, 8, 9).

Another visible difference between the stem sections is noted for *T. montanum* which presents a very large central cylinder

which does not start with a sclerenchymatous layer as in *T. polium* and *T. chamaedrys*. Moreover, the vascular bundles are almost entirely of secondary origin. The phloem fibers form a thin ring, made up of sieve tubes, attached cells and many parenchyma cells, whereas the xylem is thick and lignified and presents numerous vessels of different diameter, irregularly dispersed in the fundamental mass. Among the vessels and the cells of the xylem, there are few cells of lignified wood parenchyma, sometimes arranged in discontinuous radial rows.

For further confirmation, we also observed the features on the secondary branches of the same species. The branches contain similar cell layers, but they are thinner and differ from the main stem by the thickness of the sclerenchyma (maximum two layers) and the number of surface hairs. However, at the epidermis level of the secondary stems of *T. montanum* numerous long, multicellular and small, short secretory trichomes are visible. Moreover, in this case in the central pith, a large lacuna resulting from the disruption of the central parenchyma is observed. Sometimes this cavity is crossed by 1-2 bands of persistent medullary parenchyma (fig. 2).

With respect to *T. polium* main axis, the structure of the secondary branches differs by the following characteristics: the epidermis presents more numerous and longer surface hairs, the glandular trichomes are rarer and shorter, the collenchyma layer is thinner at the hypodermic level, the cells of the cortical parenchyma are often isodiametric; the sclerenchyma pericycle ring is thinner; the phloem and pith are thinner, but the primary xylem is slightly lignified

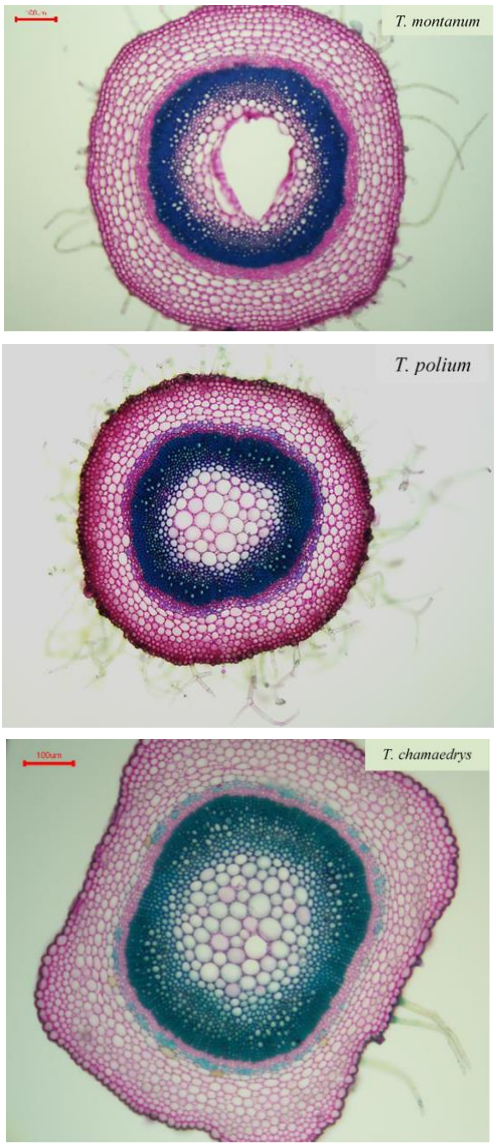

Fig. 2. The general aspect of the secondary branches obtained for the three *Teucrium* species

Leaf shape and anatomy

In general, all *Teucrium species* have the foliar lamina edges curved towards the abaxial face. Both the median vein and the lateral veins of the first order are protuber-

ant slightly to the lower face of the lamina. The lower epidermis has larger cells than the upper one, with the outer wall thicker and more intensely cutinized.

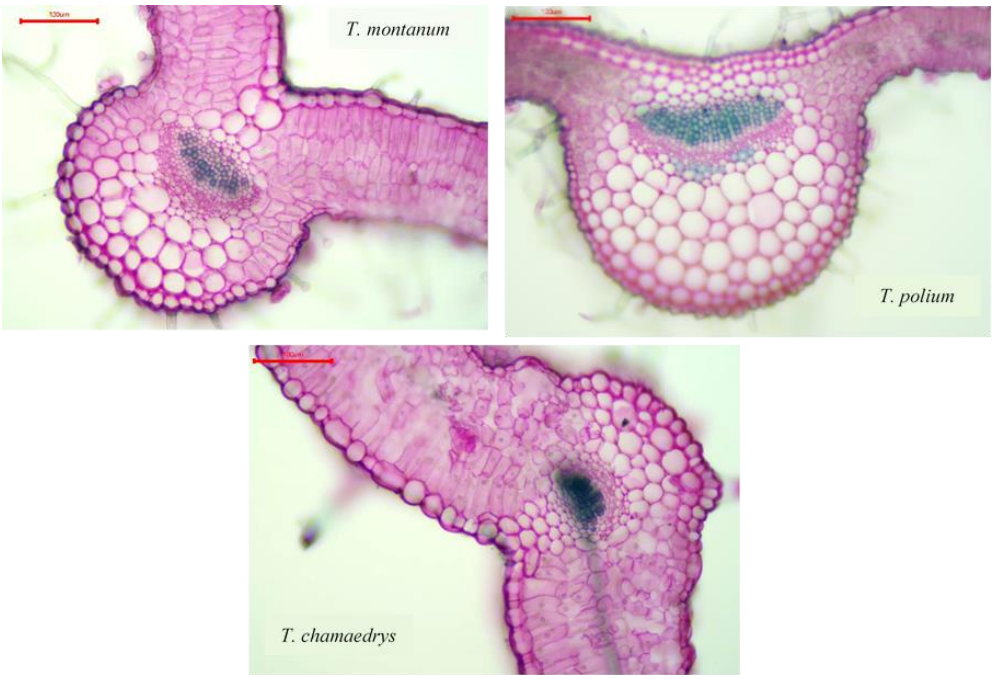

Fig. 3. The general aspect of the secondary branches obtained for the three *Teucrium* species

For *T. chamaedrys* there are surface hairs and secretory trichomes among the epidermal cells, but in smaller number on the surface unit than in the other two species, having the same structure as in the stem. Viewed from below, the lower epidermis has cells with sinuous side walls; from place to place numerous stomata are observed. The upper epidermis has cells with slightly wavy or straight walls, and the stoma is very rare. The mesophyll is differentiated into bistratified palisade tissue on the upper face and spongy multilayered tissue on the lower face, so the lamina has a hetero-facial bifacial structure. Regarding *montanum* sample, the epidermis has smaller cells on the lower face and larger cells on the upper face, the stomata are located in the lower epidermis, protruding slightly from the epidermis; so, the lamina is hypostomatic. The specific characteristics of *T. polium* leaf epidermis include isodiametric cells with the outer wall thicker and covered by a cuticular layer and the indumentum of both sides of the leaf is represented by numerous long, multicellular, uniseriate, often branched trichomes and fewer short secretory glands. Moreover, under both epidermis, there is a layer of collenchyma cells.

CONCLUSIONS

The structure plan of the analyzed organs is common to the three *Teucrium* species, with the same anatomical areas and component tissues. However, the investigated species differ in particular quan-

titative structure features such as cuticle thickness, frequency and size of trichomes, secondary xylem ring thickness, leaf mesophyll thickness, number of palisade structures and number of stomata on the surface unit lower epidermis.

Moreover, the species investigated by us differ in some qualitative traits, with significant taxonomic value, being able to distinguish the taxon when the plants are not flowering or to distinguish them when we only have fragments of the vegetative organs. The unique features that allow us to identify *Teucrium chamaedrys* plants are the bracts with homogeneous mesophyll and for *Teucrium polium* the high density of surface trichomes with branched tip. However, the stems are the main organ that are specific for *Teucrium montanum*, for which the presence of the aerial pith, the Caspary type endoderm on the bark and the lack of sclerenchyma are the characteristics necessary for identification. Nevertheless, further studies are undergoing to establish the main classes of active compounds and their pharmacologic potential.

EVALUATION OF THE NEURO-AFFECTIVE STATUS IS A DECISION FACTOR IN THE THERAPEUTIC APPROACH OF SENIOR PATIENTS WITH HIP FRACTURES (Abstract): Both the cognitive function and the affective status are fundamental geriatric cues in the objective and comprehensive evaluation of a senior patient. **Aim:** To investigate the impact of cognitive and emotional disturbances of senior patients with hip fractures over the postoperative prognostic. And recovery period. **Material and methods:** We assessed the cognition and affective status as well as the degree of fragility in group of 44 senior patients admitted in the Trauma Clinic, Iasi for hip fracture. The patients underwent preoperatively a complete geriatric evaluation, focusing on the assessment of the cognitive function (MMSE - Mini-Mental State Exam), psycho-emotional status (GDS-Geriatric Depression Scale) and fragility (Groningen-IGF fragility index). **Results:** Most of the evaluated patients were female, and over 80 years old. Moderate cognitive impairment was approximately 40% in the studied group, 27% associating fragility. The mild depressed patients, with fragile status, accounted for more than a half of the percentage of those analyzed. The patients with cognitive and affective disorders registered a negative prognostic on the postoperative evolution and during the recovery period. **Conclusions:** The results of this study confirm the need for a complete geriatric evaluation in senior patients with hip fracture, or at least the evaluation of cognitive and emotional status associated with the degree of fragility as they are considered important prognostic factors in the post-surgical and recovery period. **Keywords**: COGNITIVE STATUS, NEURO-AFFECTIVE STATUS, FRAGILITY, HIP FRACTURE, SENIOR PATIENTS.

The assessment of the degree of impairment of the cognitive and emotional functions in the elderly patient is part of the basic geriatric evaluation. The need for cognitive evaluation, depressive status and degree of frailty resides in the optimal therapeutic approach and in the prognostic value of subsequent recovery in senior patients who have suffered a hip fracture. These parameters are not only markers of the state of health at the time of evaluation, but also important prognostic factors for

post-surgical and recovery periods (1).

The analysis of the neuro-emotional status of the elderly patients admitted with hip fractures through the use of standard geriatric instruments (MMSE, GDS) can determine the optimal subsequent behavior (2).The preoperative estimation of the patient's prognosis is of particular importance for healthcare providers, for patients and their relatives, not so much in terms of treatment decisions - surgical treatment represents the gold standard - but in terms of predicting the degree of subsequent recovery (3). In this context, the Groningen frailty index is also reported as a tool for anticipating post-hospitalization complications and the actual length of hospitalization in patients with hip fracture (4).

As senior individuals remain the fastest growing group in Western societies, a further increase in the number of traumatic events is expected. Due to this demographic change, hip fractures are also a growing economic problem, which demands the efficiency not only of the clinical care, but also of pre-intervention monitoring methods (5).

Preoperative depression, preoperative cognitive deficit and frailty were related to the postoperative delirium, medication management errors, postoperative complications, such as persistent pain, longer hospitalization, institutionalization frequency, increased costs, and increased mortality (6). There are several studies that focus on different factors that can influence afflicted groups of population (7, 8), and our preoccupations are focused on new factors that can affect the outcome of surgical orthopedic senior patients, such as the pre-operative detection of neuro-affective status and the degree of fragility in elderly patients with hip fracture.

MATERIAL AND METHODS

We present a prospective study that started in June 2019, from which we present the preliminary data collected in June-October 2019, on a group of 44 patients, aged between 62-93 years, hospitalized in the Trauma Clinic "Sf. Spiridon" County Clinical Emergency Hospital Iasi, for different types of hip fractures. A comprehensive evaluation was carried out preoperatively, with special attention to assessing the neuro-affective status and the degree of fragility with the help of MMSE (Mini Mental State Examination), GDS (Geriatric Depression Scale) and GFI (Groningen Fragility Index). Depending on the score obtained in the MMSE test, patients were considered to have normal cognitive status (>24 points), mild cognitive impairment (20-24 points) or medium-severe cognitive impairment (<20 points). The patients had an IGF≥4 and were all considered fragile. Depending on the score obtained in the GDS test, patients were considered to have normal affective status (GDS= 3-6), mild depressive status (GDS=7-10), severe depressed affective status (GDS= 10-15). The completion of the questionnaires was done after obtaining the informed consent of the patient, being made by the same trained medical team.

The data were collected by a geriatric team and were analyzed using SPSS 18.0 software. ANOVA Test, Chi-square Test and Paired T-test, Kruskall-Wallis and Pearson correlation for quantitative analyze where performed. The statistical significance was defined in 95% interval of confidence ($p < 0.05$).

RESULTS

Preoperative cognitive assessment

The percentage distribution of cases

according to the cognitive evaluation showed that severe cognitive impairment was found in 11.4% of the cases, moderate cognitive impairment was noticed in 34.0% of the total study group, and slight affectation was found in 27.3% of cases; only 27.3% of cases had no cognitive impairment (fig. 1).

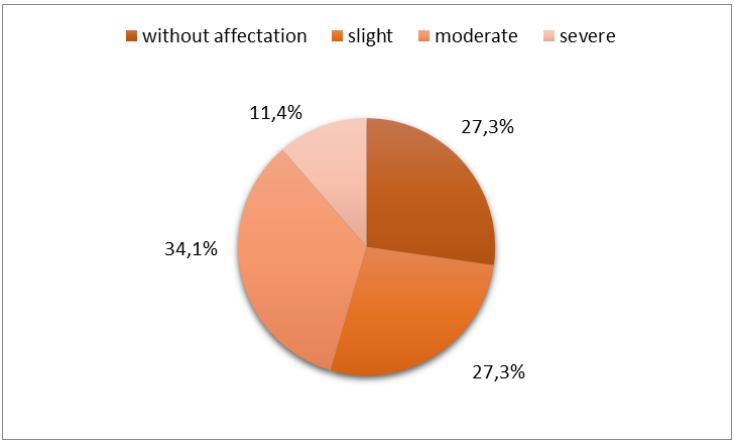

Fig. 1. The structure of the study group according to cognitive evaluation

MMSE score and age were in indirect correlation, moderate in intensity (r = -0.484; p = 0.001), noting that approximately 48% of patients had reduced MMSE scores at older ages (fig. 2).

The correlation of the cognitive impairment, as a percentage, with the marital status did not reveal statistically significant differences, 13.3% of the married persons and 20% of the divorced persons had severe neuro-cognitive impairment, and 41.7% of the patients had moderate neuro-cognitive impairment (p = 0.291) (fig. 3).

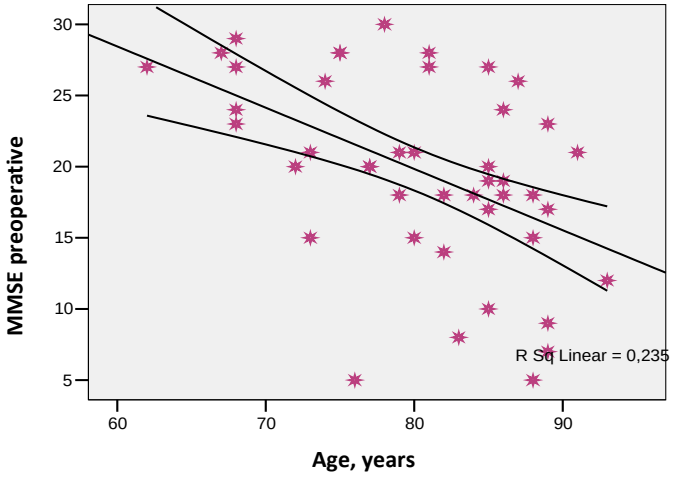

Fig. 2. Correlation of age with MMSE score

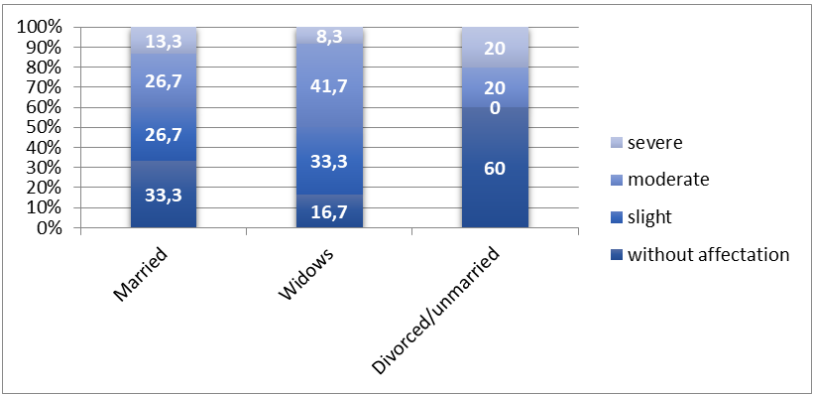

Fig. 3. Correlation of cognitive impairment with marital status

Preoperative emotional status

The percentage distribution of our cases according to emotional evaluation showed that 25% of the cases were very depressed, 54.5% of the total study group were mildly depressed and 20.5% of the cases were normal emotionally (fig. 4).

GDS score and age were apparently independent parameters (r = +0.074; p = 0.631) (fig. 5)

The correlation of emotional distress, as a percentage, with the marital status revealed statistically significant differences, 80% of unmarried or divorced people were very depressed, while 53.3% of married patients and 62.5% of widows were mildly depressed (p = 0.042) (fig. 6).

MMSE and IGF scores were in indirect correlation, reduced in intensity (r = -0.267; p = 0.08), noting that approximately 27% of the patients were associated with fragility with severe neuro-cognitive impairment, but the result cannot be extrapolated to the general population (fig. 7).

The GDS and IGF scores were in direct correlation, moderate in intensity (r = +0.590; p = 0.001), noting that 59% of the patients were associated with fragility with an extremely altered emotional status (fig. 8).

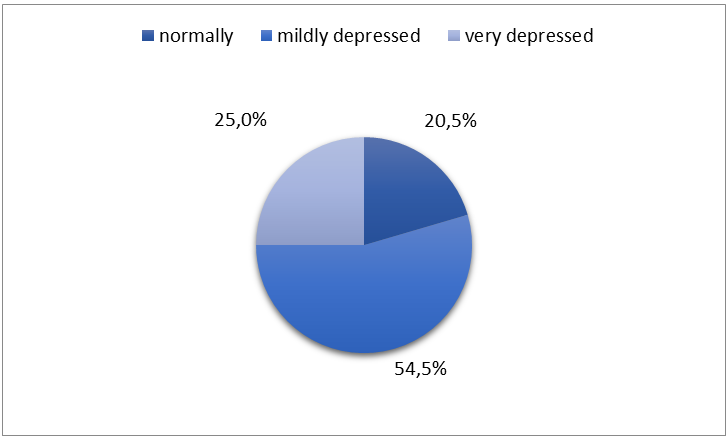

Fig. 4. The structure of the lot according to the emotional evaluation

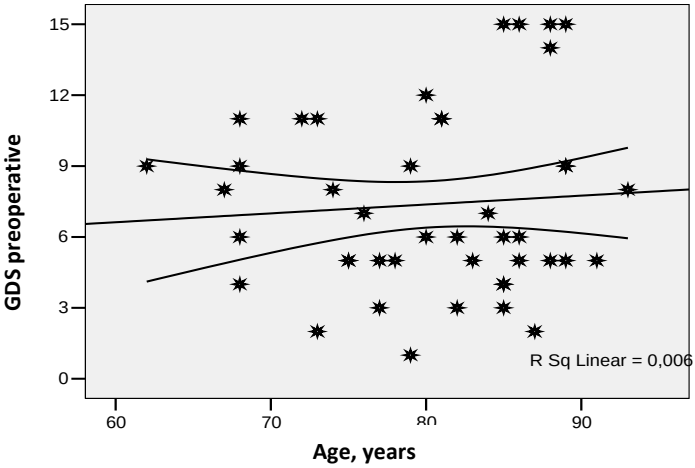

Fig. 5. Correlation of age with GDS score

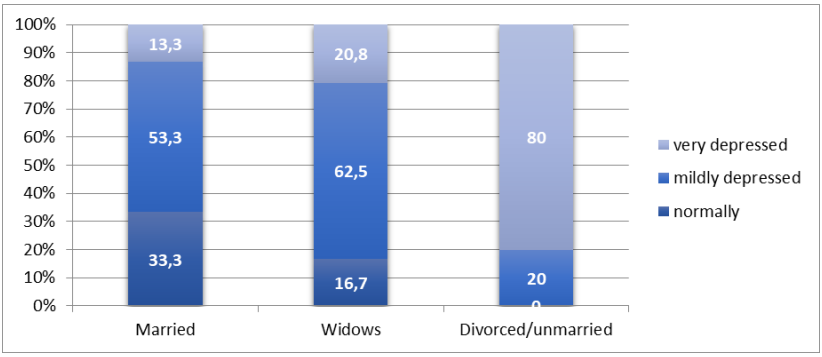

Fig. 6. Correlation of emotional affect with marital status

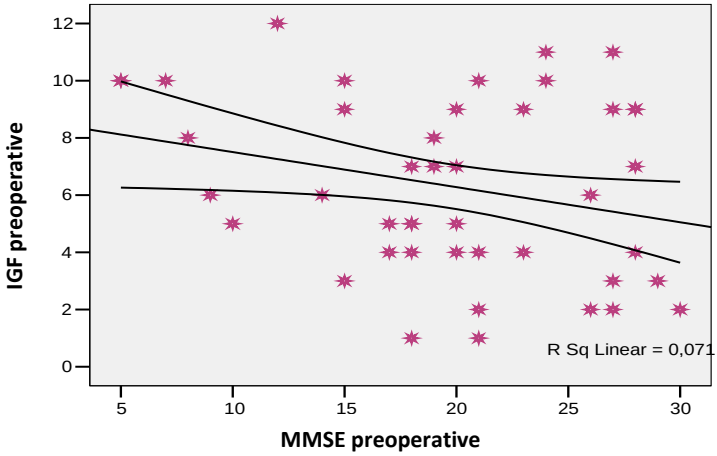

Fig. 7. Correlation of fragility with MMSE score

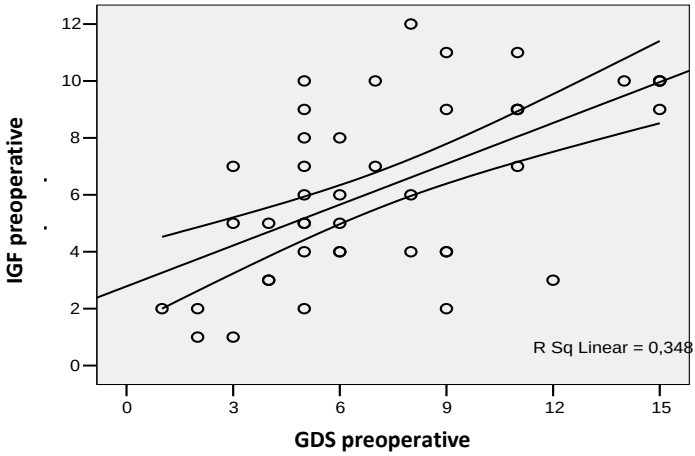

Fig. 8. Correlation of fragility with GDS score

DISCUSSION

Recent data shows the importance of performing MMSE and GDS scores in senior patients with hip fracture awaiting surgical treatment. There is an increased incidence of the alteration of functional (physical and mental) skills (9, 10) in the elderly persons exposed to such a traumatic event, despite previous functional independence (11).

It was estimated that approximately half of the seniors with hip fracture did not fully recover one year after the event, even with proper care during the recovery period (12). The one-year mortality rate for patients with hip fracture is about 25% and about one third of patients lose their independence during the same period.

There are several studies that report that there are strong connections between the onset of the traumatic event, the previous degree of depression and cognitive impairment. More than half (57.8%) of the seniors suffer from depression and cognitive impairment before the fracture (13), data confirmed by our study as well. It is important to know that trauma by itself aggravates the severity of these disorders (14, 15), which has a heavy negative impact on post-surgery mortality (16, 17), post-surgery complications and on the recovery period. A vicious circle is generated, that encompass age-associated comorbidities, the aggravation of the fragility and the prolongation of the hospitalization period (18).

Our study confirms the general opinion that the preoperative evidence of impairment of the emotional and cognitive status, in close relation with the degree of fragility, foretell a clear picture of the postoperative evolution and can advise an individualized therapeutic behavior (19), optimizing the chances of a full post-operative recovery.

CONCLUSIONS

The importance of the screening of affective and cognitive status in the senior patients that underwent a fall and a hip fracture was poorly understood and underestimated as prognostic factors in the post-surgical evolution. Our study confirms that the geriatric evaluation is very important in the preoperative assessment of these category of patients; if there is no geriatric team available, the completion of three simple questionnaires (MMSE, GDS and GFI) by any medi-

cal trainee can give valuable information about pre-surgical status of neuro-emotional and fragility status. Our data proved that there is a strong correlation between these three factors and the post-surgical evolution, complications and quality of recovery.

ENDOMETRIAL HYPERPLASIA DIAGNOSIS METHODOLOGY. CLINICAL, PARACLINICAL EXAM AND MANAGEMENT (Abstract): Factors associated with unopposed estrogenic stimulation such as obesity, exogenous hormone use endometrial hyperplasia are related to the development of the most common form of endometrial carcinoma, that is, the endometroid subtype. **Material and methods**: We selected a group of patients diagnosed with endometrial hyperplasia by endometrial biopsy and histopathological examination. The main complaint in all cases was abnormal uterine bleeding. All patients had gynecological examination, vaginal ultrasound, hysteroscopy endometrial biopsy or D&C. 32 patients had also immunohistochemical staining for Ki67, EGF, ER, PGR. **Results**: Cases with ages between 24-67 years were classified as: 100 simple hyperplasia, 10 complex hyperplasia, 43 atypical simple hyperplasia, 7 atypical complex hyperplasia. PR were 40-60% at all forms of hyperplasia, E2R were 30-40% in simple hyperplasia without atypia and 50-70% in complex hyperplasia without atypia. Correlation between immunohistochemical expression of E2R, PGR, Ki-67, EGF and body mass revealed an high immunohistochemical expression of E2R and Ki-67 in patients with hyperplasia without atypia and a low expression and high reactivity of EGF in cases with high body mass. **Conclusions**: Vaginal ultrasound and hysteroscopy are efficacious completion for histopathological diagnosis. We recommend an age/risk appropriate screening to detect risk factors and early disease in the asymptomatic patients. **Key words**: ENDOMETRIAL HYPERPLASIA, DIAGNOSTIC, MANAGEMENT

LITERATURE REVIEW OF ORAL TREATMENT OF TYPE 2 DIABETES MELLITUS

LITERATURE REVIEW OF ORAL TREATMENT OF TYPE 2 DIABETES MELLITUS (Abstract): Type 2 non-insulin-dependent diabetes mellitus (T2DM), the most common form of diabetes that affects more than 90% of diabetic patients, is characterized by insulin resistance, β-pancreatic cells dysfunction, and increased hepatic glucose synthesis. The aim of the present paper was to review data on the efficacy of conventional oral dosage forms compared to controlled oral drug delivery systems for treating diabetes. Although the number of oral antidiabetic drugs has significantly increased in recent years, clinically there are still important limitations in terms of therapeutic efficacy, tolerability, and adverse effects, particularly regarding weight gain and medium and long-term glucose control. The last generation of oral pharmaceutical formulations such as modified-release tablets overcame some limitations, while injectable formulations with glucagon-like peptide-1 receptor agonists significantly increased the effectiveness of anti-diabetic medication and significantly reduced diabetes-specific comorbidities. Metformin extended-release formulation seems to be more effective than metformin conventional-release formulation in improving glyco-metabolic control, lipid profile, and levels of some adipocytokines in T2DM. Sustained-release glipizide formulation increases the compliance compared to immediate-release glipizide because it seems to achieve similar glucose control with decreased insulin secretion and to decrease the frequency of hypoglycemic episodes. Gliclazide modified release formulation seems to be effective and safe in T2DM with suboptimal glycemic control. Modified release formulations generate other advantages such as increasing treatment compliance, lowering the dose of drug substance, and even reducing side effects. **Keywords:** NON-INSULIN-DEPENDENT DIABETES MELLITUS, CONVENTIONAL RELEASE ORAL PHARMACEUTICAL DOSAGE FORMS, MODIFIED RELEASE ORAL PHARMACEUTICAL DOSAGE FORMS.

Diabetes mellitus is a metabolic genetically or inherited disorder, with chronic evolution, characterized initially by disruption of glucose metabolism, subsequently associated with suffering and disturbance of lipidic, protidic and mineral metabolism. The diagnostic criteria defined by the standard diagnostic criteria proposed by IDF and World Health Organization (WHO) for the patient with diabetes mellitus include a *venous blood glucose higher than 126 mg/dL or 7.0*

mmol/L at fasting (fasting for at least 8 hrs.) obtained for two separate tests or by *more than 200 mg/dL (11.1 mmol/L)* measured at any time of the day in patients with symptoms of hyperglycemia or hyperglycemic crisis. Another diagnostic criterion is *the glucose tolerance test*, which requires the administration of a defined amount of glucose (75 g) followed by blood glucose level test after two hours; in this case, a *glycemia higher than 200 mg/dL* confirms the diagnosis of diabetes mellitus. Last but not least, *glycosylated hemoglobin value above 6.5% (48 mmol/mol)* completes the biochemical status of the diabetic patient (1-3). Diabetes mellitus, according to its etiopathology, is classified as: *type 1 diabetes* (autoimmune β-pancreatic cells destruction), *type 2 diabetes* (progressive loss of insulin secretion), *gestational diabetes* (usually diagnosed in the second or third trimester of pregnancy in previously clinically healthy patients). There are also other types of diabetes such as *neonatal diabetes* due to exocrine pancreatic disorders (cystic fibrosis and pancreatitis) and *iatrogenic diabetes* as a result of chronic glucocorticoid administration in transplant patients and HIV/AIDS immunosuppressed patients (2, 3).

T2DM is the metabolic disorder with the highest incidence and is considered a worldwide public health issue. According to World Health Organization (WHO) statistics, the number of diabetes patients increased from 108 million in 1980 to 422 million in 2014 and it is estimated to increase to 642 million diabetic patients in 2040 (4). According to the 2019 edition of the International Diabetes Federation (IDF) Diabetes Atlas, 463 million adults are currently living with diabetes and 700 million adults are estimated with diabetes for 2045 (5). It is important to mention that the incidence of diabetes has significantly increased in developing countries compared to the developed ones. According to the results of the PREDATORR study finalized in 2014, which aimed to assess the prevalence of diabetes in the adult population of Romania, more than 11% of Romania's population is affected by diabetes. In 2014, there were registered over 875,000 diabetic patients and in 2015 there was an increase with 8.73% in the number of patients, reaching approximately one million diagnosed patients (6).

This fact has contributed to the approval of innovative antidiabetic molecules, thus ensuring effective monitoring of antidiabetic medication, especially in patients for whom conventional antidiabetic medication does not provide a rigorous and stable glycemic control. Nowadays, the pharmacological therapy of T2DM includes the following therapeutic classes: *insulin, biguanides, sulphonylureas (hypoglycemic sulfamides), methylglinides, thiazolidinediones (glitazones), α-glucosidase inhibitors, dipeptidyl peptidase 4 (DPP-4), sodium-glucose co-transporter 2 inhibitors (SGLT2 inhibitors)* and *glucagon-like peptide 1 (GLP-1) receptor agonists* (4, 7).

Most conventional pharmaceutical dosage forms of oral antidiabetic drugs are characterized by low bioavailability, short half-life, and the need to be taken more times a day, resulting in poor patient adherence. Therefore, more research has been made in developing new controlled oral drug delivery systems. The aim of the present paper was to review data on the efficacy of conventional oral dosage forms com-

pared to controlled oral drug delivery systems for treating diabetes.

The current dosage forms for oral antidiabetic drugs are presented in first table.

TABLE I

Dosage forms for oral antidiabetic drugs

Therapeutic class	Drug name	Strength (mg)	Brand name	Pharmaceutical form	Renal impairment	Hepatic impairment	Elderly	ANMDMR approval	EMA approval
Biguanides	Metformin	1000	SIOFOR®	film-coated tablet	SRI	NO	YES	✓	✓

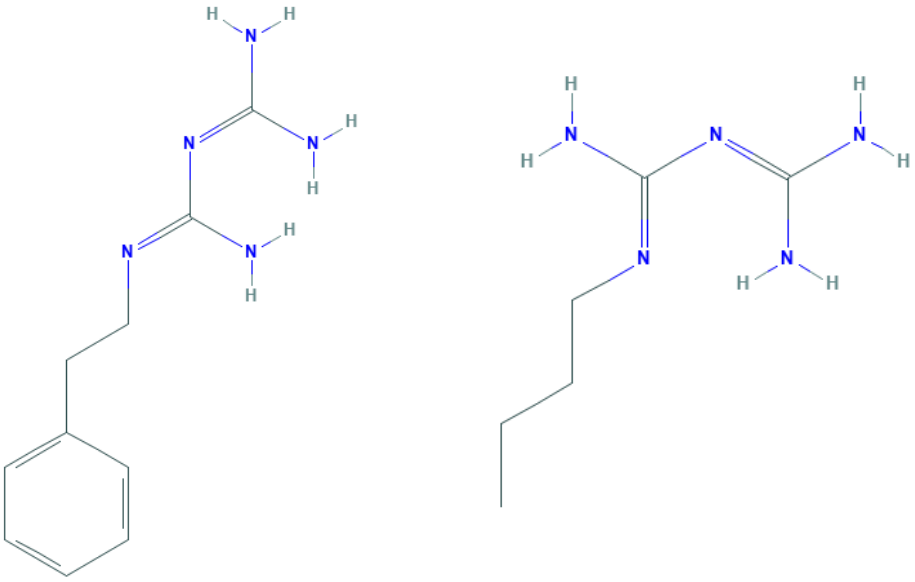
Biguanides - from conventional formulations to modified release

Since the active substance called phenformin (fig. 1a) was firstly discovered in the 1920s in the *Galega officinalis* plant extract (*French lilac*), the biguanides became the first therapeutic class of oral antidiabetic agents used in the treatment of diabetes. This compound was approved for therapeutic use only in October 1977 in the United States (US) but did not reach a major therapeutic success and was withdrawn a few years later due to the increased incidence of lactic acidosis as an adverse reaction (8). Researches in this field continued and in 1957 scientists Shapiro, Parrino, and Freedman synthesized 1-butylbiguanide (buformin) (fig. 1b), registered under the name of Silubin® formulated in delayed-release dragees/sugar-coated pills (100 mg buformin/dragee) by the German pharmaceutical company *Grünenthal*. Unfortunately, this active molecule did not offer maximum therapeutic results, being responsible for the same adverse effects as the phenformin molecule, which is the reason why it was withdrawn from the therapeutic use (9).

An important moment in the development of oral antidiabetics was the introduction of *metformin* (dimethyl biguanide HCl) molecule into therapy (fig. 2). It started to be used in European patient therapy in the mid-twentieth century, more precisely in 1957, and it was approved by the Food and Drug Administration (FDA) in the US in 1995 (3). Metformin is the first-choice oral antidiabetic drug in the management of T2DM across all age groups.



a **b**

Fig. 1. Chemical Structure of **(a)** phenformin **(b)** buformin (10)

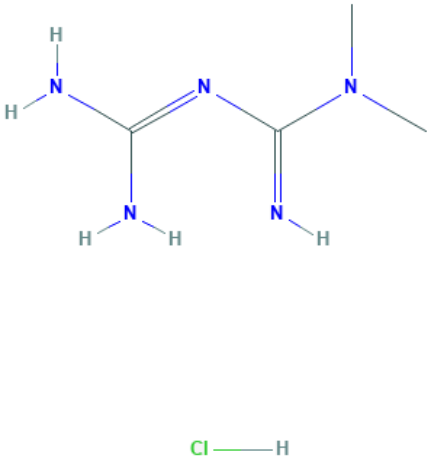


Fig. 2. Chemical Structure of metformin hydrochloride 3-(diaminomethylidene)-1,1-dimethylguanidine; hydrochloride (10)

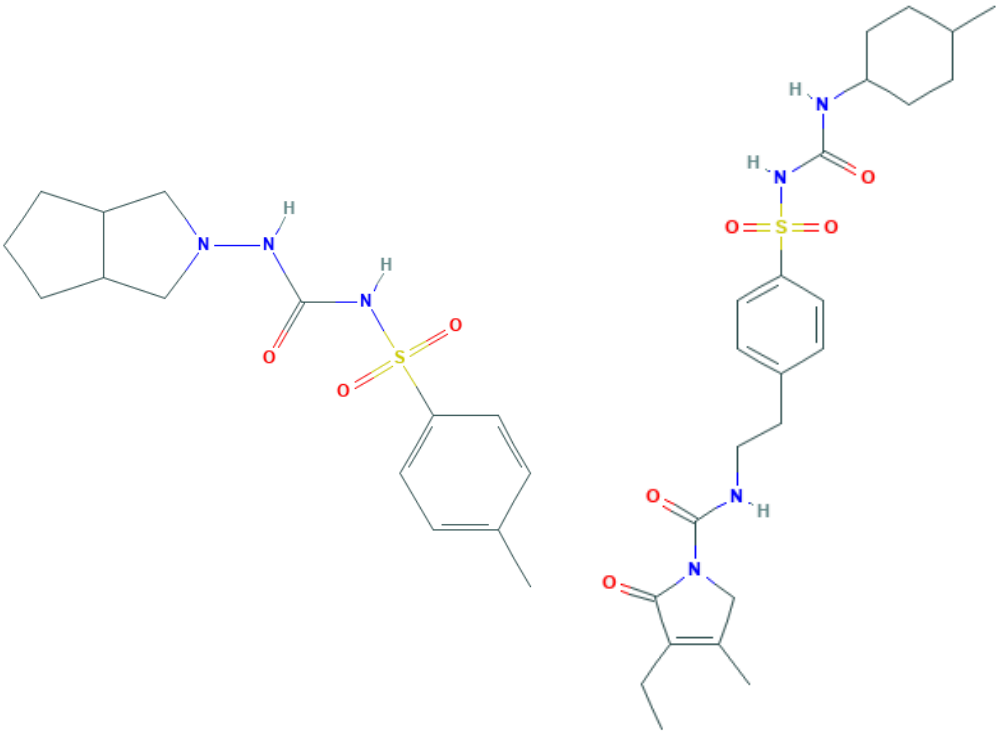
In the development of metformin clinical studies, French clinician Jean Sterne was the first diabetes specialist to introduce the molecule into therapy and gave the first commercial name of metformin conventional-release tablets, *Glucophage*® (8, 11, 12).

It has been shown that metformin alone reduces glycosylated hemoglobin by about 1.5% and is currently available as tablets with the immediate-release profile (IR) or extended-release profile (XR). The new studies of metformin pharmaceutical formulations revealed major benefits for lipid metabolism. Moreover, it was shown that prolonged-release tablets improved the glycemic control of diabetes patients. Reducing the frequency of administration at once per day in case of metformin XR formulations it was noticed an improved gastrointestinal tolerability through gradual and a controlled release of the active substance. Furthermore, by reducing the number of daily doses compliance to therapy increased significantly and the number and intensity of reported adverse reactions were also diminished (13-15).

In the Nomenclature of Medicinal Products for Human Use of the Romanian National Agency for Medicines and Medical Devices (ANMDMR), 50 pharmaceutical forms with metformin used in T2DM therapy are registered as single drug or as associations under different concentrations. Currently, metformin is the cheapest and most commonly used oral antidiabetic drug (16).

Sulfonylureas derivatives - from conventional formulations to modified release

Following the synthesis of hypoglycemic sulfonylureas derivatives, *tolbutamide* and *chlorpropamide*, which were also the first representatives, this class of oral antidiabetic drugs were intensively developed. Usually, this class of oral antidiabetic agents is recommended only in normal weight or lean patients with greater insulin deficiency, since β-pancreatic cells are still functional to secrete insulin and to lower plasma glucose levels. It is important to note that they may be associated with other oral antidiabetics, such as metformin or thiazolidinediones, but their use becomes more and more limited due to safety issues and emergence of new oral antidiabetics. The loss of β-pancreatic cell function does not allow the usage of antidiabetic sulfamides in the therapy of patients with type 1 or advanced stages of type 2 diabetes (17, 18).



a **b**

Fig. 3. Chemical Structure of **(a)** gliclazide and **(b)** glimepiride (10)

Sulfonylureas derivatives generically called sulfamides are classified into two major classes: first generation (chlorpropamide, tolazamide, tolbutamide), second-generation (glibenclamide, glibornuride, gliclazide (fig. 3 a) gliquidone, glisoxepide) and, according to some authors, third generation glimepiride (fig. 3 b) (tab. I). The second generation of sulphonylureas has a high potency and the therapeutic dose is expressed in units of milligrams of the active substance, but the maximum hypoglycemic effect is not superior to tolbutamide. Sulfamides and their metabolites have significant renal excretion, which is why caution is recommended in elderly patients and in patients with impaired renal function to avoid severe hypoglycemia (8, 19).

TABLE II

Sulfonylureas antidiabetic drugs - pharmacological characteristics

Oral antidiabetic drug	Usual daily dose (mg)	Duration of action (hrs.)	$T_{1/2}$ (hrs.)
Chlorpropamide	100-500	24-72	35
Tolazamide	100-1,000	12-18	7
Tolbutamide	500-3,000	6-10	7
Glibenclamide	2.5-15	12-16	5
Glibornuride	12.5-100	8-12	8
Gliclazide	80-240	6-12	10
Gliquidone	15-120	5-7	1.5-2
Glisoxepide	2-16	8-24	1.7
Glyburide	1.25-10	24	7-10
Glipizide	2.5-10	10-24	2-4
Glimepiride	3-6	12-12	7

Sustained-release glipizide formulation increases the compliance compared to immediate-release glipizide because it seems to achieve similar glucose control with decreased insulin secretion and to decrease the frequency of hypoglycemic episodes (21). Gliclazide modified release formulation seems to be effective and safe in T2DM with suboptimal glycemic control (22).

Oral antidiabetic drugs formulated only as conventional drug release forms

- **Thiazolidinediones (glitazones)**

The development of thiazolidinediones started from the observations of the clofibrate, ciglitazone and troglitazone derivatives (fig. 4) which were studied for their therapeutic effect on lipid profile; it was surprisingly found that these two molecules caused a decrease in blood glucose, but high hepatotoxicity though (20). In addition to the hypoglycemic effect, thiazolidinediones have a various number of pharmacological advantages, including decreasing the rate of albumin excretion, modulation of insulin resistance syndrome, lowering blood pressure, and improving the glucose tolerance threshold (7).

Based on the scientific observations of these two substances (ciglitazone and troglitazone), a new class of oral antidiabetics, called thiazolidinedione derivatives, has been developed. They are acting as agonists of peroxisome proliferator-activated receptors (PPAR). The main representatives of this therapeutic class are *pioglitazone* and *lobeglitazone* (19).

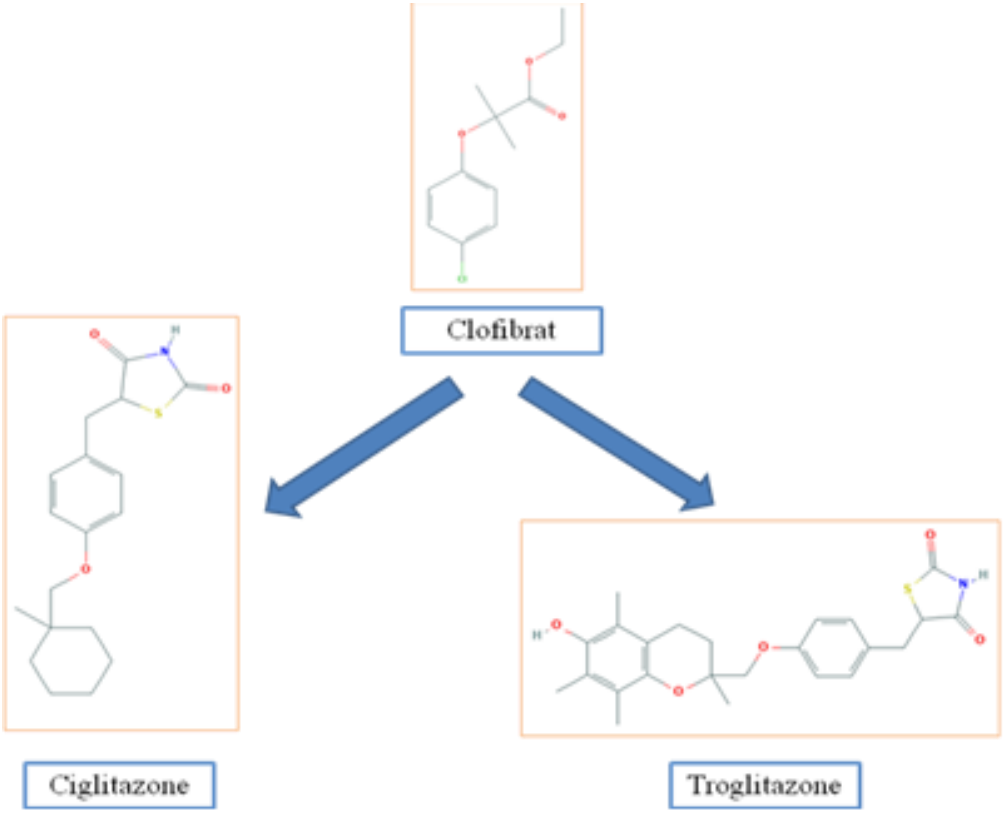


Fig. 4. Chemical structure of thiazolidinediones (10)

Pioglitazone (Actos®), the most used from this group, was authorized by the European Medicines Agency (EMEA, EMA) in October 2000 in T2DM in adult patients, particularly those who are overweight, and it is used as an adjunct to diet and exercise to improve glycemic control. Another derivative, Rosiglitazone (Avandia®) (fig. 5 a), authorized by EMEA in July 2000, was suspended in September 2010 because the benefits no longer outweighed the cardiovascular risks (23).

Lobeglitazone, a novel thiazolidinedione derivative, was approved in 2013, only in South Korea, and it is recommended in T2DM therapy. Even though the chemical structure of lobeglitazone is similar to pioglitazone and rosiglitazone, lobeglitazone was conceptually designed by modification of the rosiglitazone structure with a substituted pyrimidine. Unlike Pioglitazone, which is an agonist on both PPAR-alpha and PPAR-gamma, Lobeglitazone is a selective agonist only on PPAR-alpha. *Lobeglitazone* has a *p*-methoxy phenoxy group at the 4-position of the pyrimidine moiety leading to a more potent activity than the reference compounds (pioglitazone and rosiglitazone), with reduced side effects (fig. 5 b) (24).

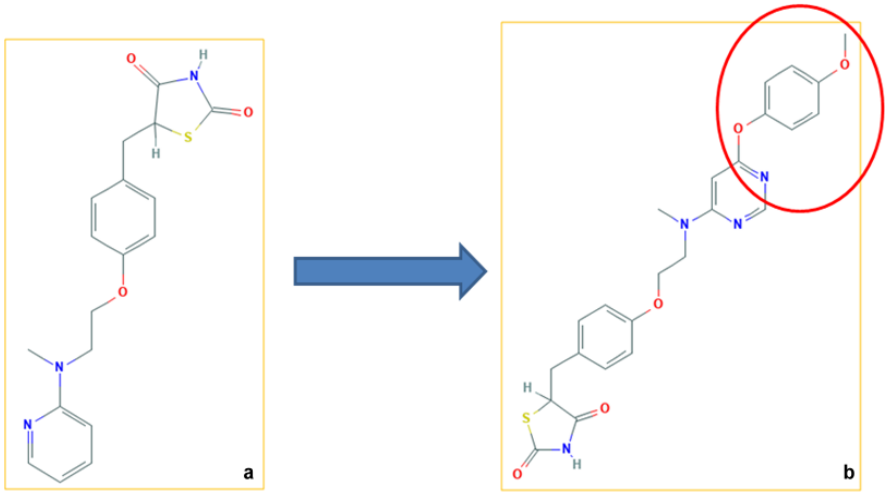

Fig. 5. Chemical Structure of **(a)** rosiglitazone **(b)** lobeglitazone (10)

➢ **Alpha-glucosidase inhibitors**

The beginning of the '90s is marked by the introduction of a new therapeutic class for patients with T2DM, α-glucosidase inhibitors, whose mechanism of action is delayed the absorption of dietary carbohydrates in the gastrointestinal tract, which generates the reduction in plasma glucose levels. Three drugs belong to this class, namely *miglitol*, *acarbose*, and *voglibose*, that were clinically approved in the US. In Romania, are used only the 50 and 100 mg film-coated tablets of *acarbose* (fig. 6), under the name Glucobay® (7, 17).

Voglibose, an unauthorized α-glucosidase inhibitor in Europe, is successfully used in Asia though. This compound was discovered in Japan in 1981, and since 1994 it has been used as an oral antidiabetic drug in T2DM therapy. *Voglibose* is used for lowering post-prandial blood glucose levels when either diet and/or lifestyle-related exercise, and other hypoglycemic agents (sulphonylureas) or insulin preparations are not able to provide adequate glycemic control.

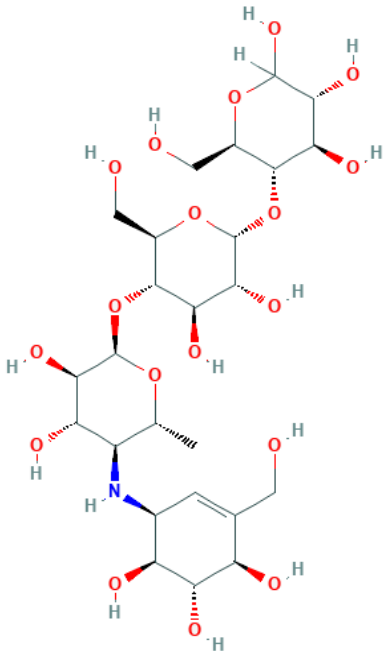

Fig. 6. Chemical Structure of acarbose (10)

This active substance produces an increased release of glucagon-like peptide 1 (GLP-1), which is an insulinotropic hormone, known to enhance insulin secretion and insulin sensitivity. Voglibose has a major advantage to acarbose, namely, it has no inhibitory activity against lactase and so, it does not cause lactose intolerance. In 2004, *voglibose orodispersible tablets* (*VODT - Voglibose oral disintegrated tablet*) were introduced into Japan, which allowed easier and faster administration of medication, in comparison with conventional oral tablets. The launch of VODT made a significant contribution to diabetic care by improving patient compliance. The development of VODT formulation brings important benefits to patients with swallowing problems, elderly patients as well as in emergencies when the patient has no access to water (25, 26).

- **Dipeptidyl Peptidase-4 (DPP-4) Inhibitors**

Dipeptidyl peptidase-4 inhibitors represent one of the newest T2DM therapy classes used as monotherapy. This therapeutic class includes drugs, such as *sitagliptin* (fig. 7), *saxagliptin*, *vildagliptin*, *alogliptin*, *linagliptin*, *gemigliptin*, *anagliptin*, *teneligliptin*, *trelagliptin*, *dutogliptin*, and *omarigliptin* (27-29). DPP-4 inhibitors have various mechanisms of action to control hyperglycemia, by stimulating the secretion of insulin from beta-cells, decreasing the secretion of glucagon from pancreatic alpha-cells, and at the same time reducing the production of glucose by the liver. The number of drugs doses administered per day is correlated with the half-life of the active substance. Thus, the sitagliptin, alogliptin, saxagliptin and linagliptin are administered in a single daily dose, while vildagliptin, with a lower half-life, is recommended for twice-daily administration. DPP-4 inhibitors may be used in combination with insulin with the great advantage of reducing the likelihood of developing hypoglycemia (3, 20).

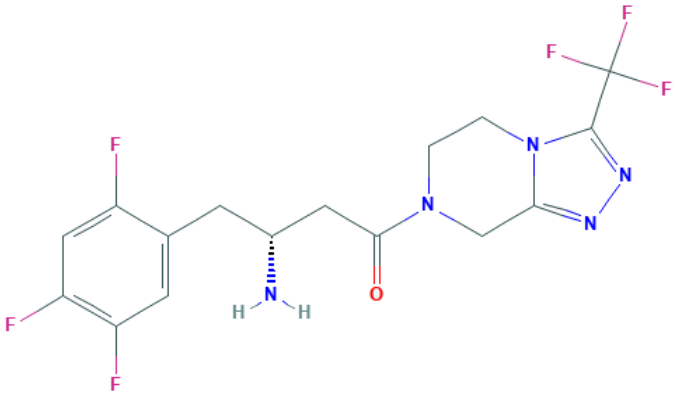

Fig. 7. Chemical Structure of sitagliptin (10)

DPP-4 inhibitors are safe, orally active, and highly tolerable, mainly in elderly patients, due to their minimal risk for hypoglycemic events.

- **Methylglinides**

Methylglinides form a class of drugs used to treat T2DM and include active substances, like *repaglinide* (fig. 8),

nateglinide and *mitiglinide*, with a mechanism of action to stimulate pancreatic secretion of insulin.

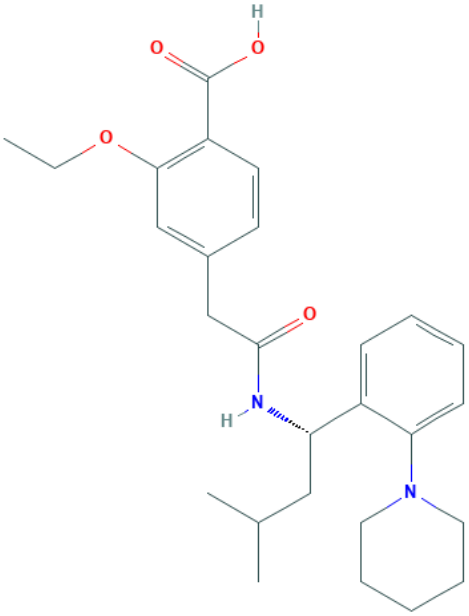

Fig. 8. Chemical Structure of repaglinide (10)

Methylglinides have a short half-life and are absorbed very rapidly from the gastrointestinal tract and therefore are recommended to be given 15 minutes before a meal. Methylglinides have the advantage that they can be used in patients who are allergic to sulphonylureas, and may reduce the risk of hypoglycemia, even if they induce similar weight gain to sulphonylureas. In case of inadequate glycemic control, they may be combined with metformin or thiazolidinediones. *Repaglinide* was introduced into therapy in 1997 as a benzoic acid derivative. Repaglinide can be administrated to patients with renal impairment, due to their excretion via feces. In 2001, EMEA approved the *nateglinide* molecule as 60, 120 and 180 mg film-coated tablets marketed under the brand name Starlix® (7, 19).

- **Sodium-glucose co-transporter 2 (SGLT-2) inhibitors**

Phlorizin, a dihydroalcohol which was found primarily in fruits of the *Pyrus communis* (pear), but also in some closely related species such as cherries and apples, is the first model for synthetic analogs of SGLT-2 inhibitors.

This compound was studied as an antidiabetic therapeutic agent as a non-selective SGLT-1 and SGLT-2 inhibitor, but it was not an effective drug because when orally consumed, it was nearly entirely converted into phloretin by hydrolytic enzymes in the small intestine. So, all the attention of researchers has since focused on the synthesis of selective therapeutic compounds SGLT-2 for T2DM treatment (30).

In January 2019, the Committee for Medicinal Products for Human Use of EMEA approved a new therapeutic indication for the *dapagliflozin* molecule (fig. 9 a), thus becoming the first oral antidiabetic drug used in type 1 diabetes mellitus as an adjuvant to insulin in patients with the body mass ≥27 kg/m^2, when insulin monotherapy does not provide adequate glycemic control (31).

Among the most commonly used compounds in the European Union are *dapagliflozin* 5 and 10 mg film-coated tablets, *canagliflozin* 100 and 300 mg film-coated tablets, and *empagliflozin* 10 and 25 mg film-coated tablets.

Empagliflozin (fig. 9 b) is the first antidiabetic drug with clinical trials in reducing the risk of cardiovascular mortality. The EMPA-REG OUTCOME® study demonstrated a 38% reduction of cardiovascular mortality risk in patients with T2DM as compared with the placebo group. Thus, empagliflozin became the first oral antidiabetic medicine administrated as monotherapy, approved by the EMEA for the reduction of cardiovascular risk (32).

CONCLUSIONS

In recent decades, oral antidiabetic drugs for T2DM has undergone a remarkable evolution from simple molecules with a hypoglycemic effect that has been accidentally discovered to complex polypeptides with multiple mechanisms of action. Although most oral antidiabetic substances are formulated into conventional (immediate) release tablets, a significant number of modified-release formulations have been introduced over the past decade, encompassing one or more drug substances thereby providing associated medication as an effective therapy in the case of patients refractory to monotherapy.

Modified release formulations generate advantages such as increasing treatment compliance, lowering the dose of drug substance, and even reducing side effects. All advances in the development of antidiabetic medication have significantly contributed to increasing the quality of life of the diabetic patient, yet T2DM remains a public health problem and a scourge affecting more and more patients.

NEWS

REGARDING LYNCH / MUIR-TORRE SYNDROMES

A “cancer predisposing syndrome” later labeled as Hereditary Non-Polyposis Colorectal Cancer (HNPCC) or Lynch Syndrome, was firstly described by Warthin, about one century ago. An increased predisposition to the development of multiple familial tumors is described as characteristic of this syndrome where visceral and cutaneous malignancies may appear at an early age namely endometrial, gastric, small bowel, ureteral and renal pelvis, ovarian, hepatobiliary tract, pancreatic, brain (Turcot Syndrome) and sebaceous glands (Muir-Torre Syndrome). The latter, a variant of Lynch Syndrome, is characterized by the presence of sebaceous skin adenomas, carcinomas and/or keratoacanthomas associated with visceral malignancies. Both Lynch Syndrome and Muir-Torre Syndrome have been recognized due to germline mutations in mismatch repair genes *MLH1*, *MSH2* and *MSH6*. To date, 56 Lynch Syndrome founder mutations dependent on *MLH1*, *MSH2* and, although less frequently found, *MSH6* and *PMS2* are described. Some of these founder mutations, principally of *MSH2* gene, have been described to cause Muir-Torre phenotype and have been traced in large and outbreed Muir-Torre Syndrome families living in different US and European territories. Due to the evidences of highly specific Muir-Torre phenotypes related to the presence of widespread *MSH2* founder mutations, preliminary search for these *MSH2* common mutations in individuals carrying sebaceous tumors and/or keratoacanthomas, at early age or in association to visceral and familial tumors, permits cost-effective and time-saving diagnostic strategies for Lynch/Muir-Torre Syndromes (Ponti G, Manfredini M, Tomasi A, Pellacani G. Muir-Torre Syndrome and founder mismatch repair gene mutations: A long gone historical genetic challenge. *Gene* 2016; 589(2): 127-132).

ILLNESS REPRESENTATIONS OF CHILDREN WITH CHRONIC DISEASES AND THEIR IMPACT ON TREATMENT ADHERENCE AND THE QUALITY OF LIFE. A NON-CATEGORICAL STUDY

ILLNESS REPRESENTATIONS OF CHILDREN WITH CHRONIC DISEASES AND THEIR IMPACT ON TREATMENT ADHERENCE AND THE QUALITY OF LIFE. A NON-CATEGORICAL STUDY (Abstract): The identification of the connections between illness representation, the quality of life, and treatment adherence, among the children diagnosed with diverse chronic diseases. Furthermore, we wished to see whether there were differences by gender at the level of the three variables. **Material and methods:** 94 children - 52 boys and 42 girls - with a mean age M = 13.63 ± 2.68, filled out the *Perceptions Questionnaire-Revised*, the *Self-Regulation of Medication Adherence Battery*, and the *Pediatric Quality of Life Inventory*™ Version 4.0. **Results:** Preponderantly, the correlations identified between the three variables are negative. We have not identified any significant differences by gender, in what concerns illness representations. However, girls have higher control over treatment adherence (M girls = 3.30, M boys = 3.49, p = 0.035) and lower emotional functioning compared to boys (M girls = 62.14, M boys = 73.40, p = 0.016). **Conclusions:** The higher level of illness identity, illness coherence, and personal control among children, the more likely for them to adhere to treatment. Furthermore, the higher control over the treatment, the greater motivation of children to adhere to treatment. Consequently, practical interventions should focus on instilling the children's perceived control over their treatment.
Keywords: ILLNESS REPRESENTATION, QUALITY OF LIFE, ADHERENCE, CHILDREN CHRONIC DISEASE.

According to the National Health Report for Children and Young People in Romania (1), in 2017 the prevalence of chronic diseases among children was 26.2%. The percentage varies - at international level - between 13-27%, by the definition considered for chronic disease (2, 3). When we discuss chronic disease and treatment, we must consider treatment adherence - depending on which we further model the evolution of a patient's health state (4).

Treatment adherence has significant implications on health outcomes; low levels lead to an increase in mortality and a

decrease in the quality of life (5). This is a complex construct, influenced by multiple factors, referring to the extent to which a person observes the recommendations of a health specialist. (6) Among the factors with a significant impact on treatment adherence, it is worth noting the beliefs of a person in what regards their medical condition (7). These representations are subjective perceptions, more or less close to the scientific and medical objective reality (8). The model comprising the constitution and evolution of this construct, its connections with other important variables - such as the mechanisms of adapting to illness and the outcomes obtained - is the Common-Sense Model, theorized by Leventhal and his collaborators (9). These representations are in direct connection with the coping mechanisms used by a person, further impacting treatment adherence and the outcomes obtained, such as the quality of life (8, 10).

The quality of life has been provided with a variety of definitions over time, but its central point supports the multidimensional character of the concept and the optimal functioning of a person in three main fields: physical, psychological, and social (11).

Scientific literature supports the hypothesis of significant correlations between illness representations and the quality of life (12-15), between illness representations and treatment adherence (4, 7, 10, 13, 16), and treatment adherence and the quality of life (17-22). However, among children and adolescents, the chronic disease representations are still not well understood, while their connections with treatment adherence and the quality of life are not sufficiently known (4, 6, 23). Consequently, the purpose of this study is to point out - in a non-categorical framework - the relationship between illness representations, treatment adherence, and the quality of life, as well as the gender differences in what regards the three listed variables.

MATERIAL AND METHODS

Participants

This study has included 94 children diagnosed with a chronic disease: 52 boys and 42 girls. Among the chronic diagnoses of children, the most common are kidney chronic disease, diabetes, epilepsy, scoliosis, chronic tonsilitis, and asthma. Children are aged between 8 and 18, with a mean of $M = 13.63 \pm 2.68$. For the participation in this study, the consent of the child's legal tutor was obtained beforehand.

Instruments

Illness Perceptions Questionnaire - Revised (24) contains 38 items, for which the subjects are asked - on a Likert scale - the assess the degree of agreement (from strongly disagree, to strongly agree). The items are grouped into five dimensions: timeline (two components: acute/chronic and cyclical), control (two components: personal control and treatment control), consequences, illness coherence, and emotional representation, as well as 7 subscales. The α Cronbach coefficient obtained, for all dimensions, values between 0.60 and 0.96.

The Self-Regulation of Medication Adherence Battery (25) comprises 10 items referring to the motivation to be medication adherent (3 items), perceived control of medication adherence (4 items), and support from the caregiver (3 items). The α Cronbach coefficient for the 10 items has the value 0.75.

Pediatric Quality of Life Inventory™ Version 4.0 (26) includes 23 items as-

sessing physical functioning, emotional functioning, social functioning, and school functioning of children and of adolescents. The four scales make up two dimensions: physical health and psychosocial health. Internal consistency for the entire instrument is Cronbach's $\alpha = 0.92$.

Statistical analyses

The distribution of variables has been assessed through the Kolmogorov-Smirnov test. The not normally distributed variables ($p > 0.05$) are as follows: illness identity, illness-related symptoms, personal control, treatment control, illness coherence, and support from the caregiver. We have tried to normalize these variables using logarithms; this worked only for the variable of personal control. In order to identify the relationship between the variables, we have determined Pearson's and Spearman's correlations. The differences determined by gender were identified by applying the t tests for independent samples (normally distributed variables) and the Mann-Whitney test (not normally distributed variables). Furthermore, rank regressions were performed.

RESULTS

Upon analyzing the correlations between the dimensions of illness representation and the quality of life (tab. I), we have identified the following significant relations: the dimension of illness causes correlates significantly and negatively with emotional functioning ($r = -0.359$, $p < 0.001$), social functioning ($r = -0.297$, $p = 0.004$), school functioning ($r = -0.270$, $p = 0.011$), psychosocial functioning ($r = -0.316$, $p = 0.003$) and total score of the quality of life ($r = -0.252$, $p = 0.019$).

TABLE I

Correlations between illness representation and the quality of life

Variables	Causes	Acute/chronic timeline	Consequences	Cyclical timeline	Emotional representation	Personal control
Physical functioning	-.147	-.030	-.169	-.218*	-.225*	-.200
	.165	.774	.110	.038	.032	.057
Emotional functioning	-.359**	.158	-.082	-.196	-.270**	-.270*
	.000	.132	.442	.064	.010	.010
Social functioning	-.297**	.107	-.375**	-.109	-.351**	-.050
	.004	.304	.000	.300	.001	.633

	.003	.171	.041	.078	.009	.037
Quality of life total score	-.252*	.085	-.224*	-.230*	-.276**	-.258*
	.019	.432	.037	.032	.010	.016

**. significant at the 0.01 level (2-tailed).

*. significant at the 0.05 level (2-tailed).

The dimension of consequences correlates with social functioning ($r = -0.375$, $p < 0.001$), psychosocial functioning ($r = -0.218$, $p = 0.041$) and total score of the quality of life ($r = -0.224$, $p = 0.037$); cyclical timeline correlates significantly with

physical functioning (r = -0.218, r = 0.038) and total score of the quality of life (r = -0.230, p = 0.032); emotional representation obtained significant correlations with physical functioning (r = -0.225, p = 0.032), emotional functioning (r = -0.270, p = 0.010), social functioning (r = -0.351, p = 0.001), psychosocial functioning (r = -0.277, p = 0.009) and total score of the quality of life (r = -0.276. p = 0.010); the dimension of personal control also recorded three significant correlations with emotional functioning (r = -0.270, p = 0.010), psychosocial functioning (r = -0.223, p = 0.037), and total score of the quality of life (r = -0.258, p = 0.016). Despite our expectations, all these correlations are negative. Significant results, obtained for the Spearman correlations, were obtained between illness identity and social functioning (ρ = 0.305, p = 0.004), and psychosocial functioning (ρ = 0.260, p = 0.017); the variable of illness-related symptoms correlated significantly with emotional functioning (ρ = 0.342, p = 0.001), school functioning (ρ = 0.337, p = 0.001), and psychosocial functioning (ρ = 0.266; p = 0.013); while illness coherence correlates with social functioning (ρ = 0.255, p = 0.013). All the correlations are positive.

Upon analyzing table II, it is worth noting that the dimension of adherence motivation did not record statistically significant correlations with any normally distributed dimension of illness representation. The dimension of adherence control correlates significantly with acute/chronic timeline (r = -0.425, p < 0.001), consequences (r = -0.214, p = 0.040), and personal control (r = 0.282, p = 0.007). The total adherence score correlated significantly and negatively with acute/ chronic timeline (r = -0.263, p - 0.011). The application of the Spearman correlations have highlighted the following: the dimension of support from the caregiver correlates significantly with consequences (ρ = 0.323, p = 0.002), illness identity correlates with support from the caregiver (ρ = -0.384, p < 0.001), adherence control (ρ = -0.203, p = 0.055), and total adherence score (ρ = -0.463, p < 0.001). Illness-related symptoms correlates significantly and negatively with adherence motivation (ρ = -0.302, p = 0.004), support from the caregiver (ρ = -0.308, p = 0.003), adherence control (ρ = -0.240, p = 0.022), and total adherence score (ρ = -0.448, p < 0.001). The dimension of treatment control correlated with adherence motivation (ρ = 0.263, p = 0.010), support from the caregiver (ρ = 0.261, p = 0.012) and total adherence score (ρ = 0.235, p = 0.024). The variable of illness coherence did not record any significant correlation.

Furthermore, we have analyzed the connections between treatment adherence and the quality of life, while the significant outcomes were illustrated in third table.

Upon analyzing the significant correlations identified between the dimensions of treatment adherence and of the quality of life, it is worth noting that they are negative.

In order to identify potential differences by gender, in what concerns the dimensions of illness representations, of the quality of life, and of treatment adherence, the t tests for independent samples were used. Table IV features only the significant outcomes (p < 0.05).

Two rank regressions were performed, in order to identify the significant predictors of the quality of life and of treatment adherence. For both criteria, there were the same models, as follows: model 1 comprising illness causes, acute / chronic timeline, consequences, cyclical timeline, emotional representation, and personal control; for model 2, the variable of age was added. In

case of the adherence criterion, both models were statistically insignificant (Model 1: F = 1.876, p = 0.095; Model 2: F = 1.750, p = 0.109). For the quality-of-life criterion, both models were significant (Model 1: F = 3.861, p = 0.002; Model 2: F = 3.673, p = 0.002). Model 2 explains the highest variance percentage of the criterion, namely, 17.9%, whereas model 1 explains 16.6% of the quality-of-life variance.

DISCUSSION

Most connections identified between the dimensions of variables illness representation and the quality of life are negative. The more underlying causes identified for illness, the greater number of consequences, cyclical timeline and stronger emotional representation, the higher impairment of the quality of life. It is surprising that even the connection of personal illness control correlates negatively with the children's quality of life. The need to exercise high illness control may be associated with worsened symptoms and, implicitly, with a decrease in the quality of life. However, based on the positive correlations, the clearer illness identity among children (6), the more they manage to identify the symptoms related to their illness and they record higher illness coherence and the better they function at certain levels.

On the other hand, the higher perceived personal control of the disease among children, the higher control over treatment adherence (25). An important particularity of chronic children is that they need support to follow the treatment. In this study, as the illness consequence increase, children feel that they benefit from their caregiver's support for treatment adherence. Furthermore, as treatment control improves, children are more motivated to adhere to treatment. This outcome has serious implications in adolescence because their responsibility in treatment management also increases. Consequently, interventions in practice could focus on instilling children's perceived control over their treatment. Furthermore, age is an important variable because it also improves the explanatory efficiency of the regression model, in what regards the quality of life.

In accordance with the findings reported by Barakat (27), all the connections obtained between the dimensions of the quality of life and treatment adherence variables are negative. The explanation provided by the authors is that better treatment adherence may interfere with certain activities contributing to the children's quality of life (27). Finally, we add that treatment adherence may be associated with secondary symptoms, which may explain the decrease in the quality of life; in this respect, a caregiver's support may be perceived as excessive insistence. The quality of life may be affected by the presence of illness or by its treatment; thus, it becomes necessary for it to be integrated in the assessment performed by physicians in order to determine the prognosis of a medical condition (12).

By gender, differences were identified in case of adherence control and emotional functioning variables. More precisely, girls have higher control over treatment adherence, but lower emotional functioning compared to boys. In what concerns illness perception, no significant differences have

been found (28).

An important limit is related to the non-representative sample and to the instrument assessing treatment adherence, for which we have not identified statistical data.

Although surprising, the negative correlation between treatment adherence and the quality of life has not been identified now for the first time in scientific literature. Consequently, studies clarifying the potential mechanisms and variables within this correlation are recommended. Furthermore, the coping mechanisms used by children should be studied in relation to illness representation, the quality of life, and treatment adherence.

CONCLUSIONS

Considering the connections identified between the variables featured in this study, our recommendation is to identify in practice the children's subjective illness perceptions. Furthermore, both the medical professionals and the children's caregivers should focus on instilling children's perceived control over their treatment, mostly during adolescence, when their responsibility in treatment management increases. Psychological support should focus on emotional management of the disease, especially among girls who appear to be more strongly impacted. Also, both the children's caregivers and the medical team should pay attention to the quality of life of children, even when they are adherents to treatment, and to integrate into the lives of chronically ill children activities that increase their well-being.

CONE BEAM COMPUTED TOMOGRAPHY (CBCT) ASSESSMENT OF INCISOR ROOT RESORPTION (IRR) ASSOCIATED WITH IMPACTED MAXILLARY CANINES (IMC). LITERATURE REVIEW (Abstract): CBCT assessment of impacted canine improves canine localization to adjacent teeth and provides higher level of confidence in the treatment plan compared to 2D images. However, there is conflicting evidence to support using CBCT as a routine first-line imaging method in patients with impacted maxillary canine and incisor root resorption. Consequently, there are doubts regarding difference in diagnostic and treatment planning between the use of conventional 2D and CBCT sets. Therefore, the present review will attempt to summarize the new aspects regarding the benefits of three-dimensional (3D) diagnostic techniques (cone-beam computed tomography, CBCT), including the accuracy of localization of impacted canine and the detection of the degree and location of root resorption of maxillary incisors. **Keywords**: IMPACTED CANINE, INCISOR ROOT RESORPTION, CONE BEAM COMPUTED TOMOGRAPHY.

Permanent maxillary canines are the second most frequently impacted teeth after the third molars. At the same time, maxillary canines are important esthetically and functionally. An impacted canine is usually diagnosed on routine examination, and it can cause additional problems during the development and eruption of the impacted tooth and the neighboring teeth (1).

Root resorption of the maxillary incisors caused by impacted canines is a relatively common phenomenon and is defined as a condition associated with either a physiological or pathological activity of the tooth resorbing cells, which results in loss of cementum and dentine. Root resorption is very difficult to treat and usually requires extraction of the affected tooth (2).

CBCT (cone-beam computed tomography) provides an alternative to traditional CT (computed tomography) systems using a significantly less radiation dose and shorter acquisition scan times, and it provides valuable information regarding impacted canines with submillimeter spatial resolution images of high diagnostic quality to better understand and improve treatment at lower cost (3-6).

The present paper attempts to review in the recent literature (last 15 years) the

three-dimensional assessment of impacted canines and incisor root resorption using cone beam computed tomography.

MATERIAL AND METHODS

We have searched the MEDLINE database through *PubMed* by using following key words in English "impacted canine" [All Fields], "incisor root resorption" [All Fields], "cone beam computed tomography" [All Fields].

The selection criteria and filters were the year of publication 2005 to 2020, longitudinal, transversal and cohort studies, systematic reviews, and meta-analysis. Excluding criteria: case reports, irrelevant articles, laboratory studies, articles in languages other than English, abstracts. The Pub Med search identified 48 articles, but only 25 met our inclusion criteria (fig. 1).

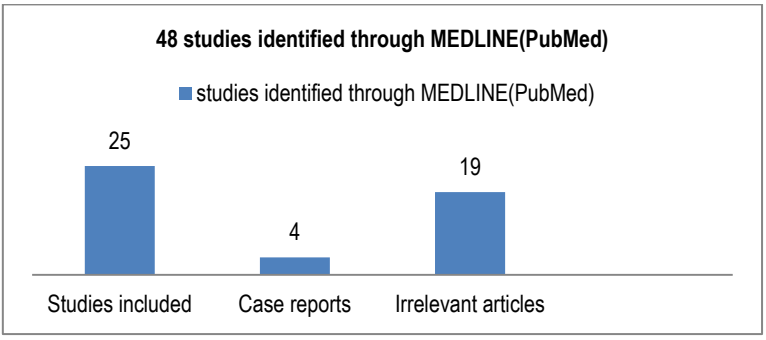

Fig. 1. Studies identified on PubMed

DISCUSSION

In a 2018 study (7) which included 608 CBCT reconstructions the pathology that was most commonly caused by impacted teeth was periodontal bone loss (44.4%), followed by root resorptions (33.3%), cysts or tumors (8.6%), and tooth decays (2.3%).

3D volumetric imaging of impacted canines can show the following: presence or absence of the canine, size of the follicle, inclination of the long axis of the tooth, relative buccal and palatal positions, amount of bone covering the tooth, 3D proximity and root resorption of adjacent teeth, condition of adjacent teeth, local anatomic considerations, and overall stage of dental development (6).

a. CBCT assessment of impacted canines (tab I.)

In the first CT study of 113 impacted canines, Bjerklin and Ericson (8) reported more buccally placed canines, with respective numbers of 42% (palatal), 40% (buccal), and 18% (in line with the arch).

Liu *et al*. (9) found in 210 patients utilizing CBCT that impacted canines were located palatally in 41%, labially in 45%, and midalveolus in 14% of cases. The location of impacted maxillary canines varied greatly in 3 planes and showed incisor root resorption in 27% of lateral incisors and 23% of central incisors.

A CBCT study by Walker *et al*. (6) found that 25 of 27 impactions (n=19 patients) were located palatially, and two were located labially. He found lateral incisor root resorption and central incisor root resorption in 18 and 3 of those cases, respectively.

A Polish study (10) suggested that CT scan allows the assessment of the degree

and extent of resorption of lateral incisor roots adjacent to impacted maxillary canines. Of a total of 54 impacted permanent maxillary canines, 41 (75.9%) were positioned palatally, 10 (18.5%) buccally, and 3 (5.6%) horizontally. There were 31 cases (64.6%) of lateral incisor root resorption, of which in 18 (58.1%) resorptions was deep, and in 13 (41.9%) it was slight. Age of patients is a significant factor which has an effect on occurrence of damage to incisor roots. Also, the position of impacted canines has an effect on the process of resorption of incisor roots.

TABLE I
Studies reporting 3D assessment of impacted canines

Authors	Year		Number of canines	Location of impacted canines					
				Palatal		Buccal		Middle	
				N	%	N	%	N	%

da Silva Santos LM *et al.*	2014		79	53	67.1	17	21.5	9	11.4
Dağsuyu *et al*	2015		140	76	54.3	25	17.9	39	27.8
CTT Ngo *et al.*	2018		86	58	67	24	28	4	5
Kalavritinos *et al.*	2020	Right	42	20	46.6	7	16.6	15	37.7
		Left	49	27	55.10	5	10.2	17	34.6

Another study (11) comprises 113 patients with CBCT scans, and 134 impacted canines were analyzed retrospectively. In the patients evaluated, 69 impacted canines were located palatally (51.49%), 41 labially (30.60 %), and 24 (17.91 %) in the middle of the alveolar process. Root resorptions were found in 34 lateral incisors (25.37 %), 7 central incisors (5.22 %), 6 first premolars (4.48 %), and one second premolar (0.75 %).

In a Chinese study (12), pretreatment CBCT scans of 170 Chinese subjects (ages, 12-30 years; mean, 14.5 years) with impacted maxillary canines (101 buccal and 69 palatal impactions) were used.

Of 42 CBCT reconstructions (13) of impacted canines undergoing orthodontic treatment, 17 (40.4%) had no root resorption, 15 (35.7%) showed slight root resorption, 6 (14.2%) moderate resorption, and 4 (4%) severe root resorption of the adjacent lateral incisor. In only one individual both central and lateral incisors were resorbed. The most frequent location of impacted canines was palatal, mesial, and gingival.

In a Korean study (14), the maxillary canine impaction occurred more frequently on the buccal side (140 canines) than the palatal side (46 palatally canines) and more frequently in females than in males by a 1.5-fold margin. Tooth resorption in the CT images showed a large percentage value of 49.5 %. The impacted angulation evident in the panoramic radiographic image did not have any statistically significant relations

with either the impacted position or the root resorption.

Forty-six patients with impacted teeth undergoing orthodontic treatments in Tongji Hospital (Wuhan, China) were examined (15). Most of the upper impacted canines (40.2%) were located buccally, 37.6% were located palatally, while 22.2% were located in midalveolus. Adjacent tooth root resorption of 28.26 % was in the upper lateral incisors while 17.39% in upper central incisors, but no lower root resorption was found in the samples.

In a retrospective radiographic (CBCT and panoramic) study (16) of 64 patients with 86 MICs, most of the positions of MICs were palatal (67%), followed by labial (28%) and midalveolus (5%). The association between sectors of the MICs on panoramic images and the labio-palatal position of the MICs on CBCT was statistically significant. Root resorption of adjacent incisors showed a significant difference according to sector location. Labio-palatal position of MICs and resorption of permanent incisors might be predicted using sector location on panoramic radiographs .

A retrospective study (17) examined the CBCT scans of 140 MICs in 102 patients (43 males, 59 females). Maxillary canine impaction was more frequently seen in female subjects than in male subjects. Lateral incisors were more frequently affected than first premolars, and slight resorption was more frequently seen in adjacent teeth. CBCT assessment of MICs can provide accurate measurements of angular, linear, and resorption parameters .

b. 3D position of maxillary canine impactions and the influence on adjacent incisor root resorption (tab II)

The use of CBCT in patients with impacted canines has diagnostic potential and can be a genuine method used to rectify, diagnose, and suggest a treatment for incisor root resorption (18).

TABLE II

CBCT studies reporting incidence of root resorption caused by MIC

Authors	Year		Percentage % of teeth reporting root resorption			
			Lateral Incisor	Central incisor	First premolar	Second premolar

		Left side	6.4			
Alemam AA *et al.*	2020	Palatal displayed canines	74	18		
		No displayed canines	25.5			

In a recent study (19), CBCT provided improved detection rates (63%) of root resorption associated with impacted canines. There was no difference in resorption rates between buccally and palatally impacted canines. The resorption scale developed by Jawad Z *et al*. (Three-Dimensional Leeds Orthodontic Root Resorption Target Scale) (29) was intended to address the subjective nature of reporting the CBCT images taken to assess root resorption associated with impacted teeth.

In one study (20) the angulation of the canine was steeper on the labial side than on the palatal side, but root resorption of adjacent laterals was not different. There were no statistically significant differences in the amount of root resorption of the laterals when the canine was evaluated according to localization and angulation .

In contrast, another study (21) concluded that the risk of resorption of the lateral incisor is not linked to the buccal or palatal situation of the canine. The risk is greater when the canine is vertically above the lateral incisor root and close to the median palatine suture, suggesting a mechanical blockage by the apex of the lateral incisor.

Sixty-one patients presenting with unilateral or bilateral impacted maxillary canines were evaluated in a university clinic in Athens, Greece using CBCT reconstructions (22). They concluded that there is no relationship between lateral or central incisor root resorption and the shape and width of the impacted canine follicle. Lateral incisor root resorption due to canine impaction occurred in 18.5% of the examined cases. The percentage of impacted canines causing root resorption to both central and lateral incisors on the ipsilateral side is very low. Younger patients appear to have the left canine located more often in the middle of maxillary bone, whereas older patients have left canines located more often in the palatal or buccal side of the bone. There is a tendency for younger ages to demonstrate resorption in the apical or middle third of the tooth, whereas the tendency for older patients is to demonstrate resorption at the incisal third. There is a positive correlation between the appearance of resorption on the lateral incisor and the angle between the axis of canine and adjacent lateral incisor.

In a Chinese study (12) root resorption was significantly more prevalent in the canine-impaction subjects and the side of impaction, with overall prevalence rates of 27%, 18%, and 10% at the maxillary lateral incisor, the central incisor, and the first premolar, respectively.

CBCT images for 107 palatally displaced canines (PDCs) and 51 fully erupted nondisplaced canines (NDC) were analyzed for the presence of incisor root resorption (IRR) (23). Root resorption affected 74% of lateral incisors adjacent to PDCs and 25.5% of lateral incisors adjacent to NDCs. The most common location of the root resorption is lingual surface, which can be explained by the palatal position of displaced canines. The second most common location was the distal surface. Canines in contact with adjacent incisor roots was the only risk factor detected for PDC-IRR. Very good predictive discrimination (83%) emerged for PDC-IRR subjects. Predictors of PDC-IRR were canine contact with adjacent incisor, size of canine dental follicle, and presence of peg-shaped lateral incisor.

c. CBCT assessment of incisor root resorption location (tab III)

CBCT provides accurate information about the location of impacted canine and

prevalence and degree of root resorption of neighboring teeth with high interrater correlation. This information is of great importance for surgeons and orthodontists for accurate diagnosis and interdisciplinary treatment planning (11, 24).

TABLE III

Studies reporting incisor root resorption location on CBCT

Authors	Year	Incisor root resorption location		
Ericson and Kurol	2000	1/3 middle root	Labial surface	Lingual surface
Yan B *et al.*	2012	1/3 apical root	1/3 middle root	
Doğramaci EJ *et al*	2015	The apical third and palatal surface		
Schroder *et al.*	2018	All root levels and surfaces of teeth associated especially 1/3 apical root		
Alemam AA, *et al.*	2020	1/3 middle root	Lingual surface	
Kalavritinos *et al.*	2020	Young patients -1/3 apical or 1/3 middle of the root		
		Older patients -1/ 3 incisal root		

Using CT, Ericson and Kurol (25) reported that maxillary incisor resorption occurred most commonly in the middle third of the roots, on the labial or lingual surfaces, with 60% of the resorbed lateral incisors and 43% of the resorbed central incisors that have pulpal involvement.

Root resorption in maxillary incisors was correlated with their contact with maxillary canines during eruption. Delayed eruption or treatment of impacted canines may lead to resorption of the adjacent lateral and central incisors. All root levels and surfaces of teeth associated with impacted maxillary canines can be resorbed to different levels of severity, but the apical one-third with slight resorption is the most common (26).

Data from a 2015 study (27) showed that a total of 110 impacted maxillary canine teeth resorbed 120 adjacent teeth, including 14 premolars and one permanent molar. The apical third and palatal surface were commonly involved. Fifty per cent of the resorptive lesions were mild, 20% moderate and 30% severe. Neither age nor gender influences the number, location or severity of the resorption .

Predominantly affecting the apical third of all teeth, impacted canine-associated root resorption, if present, reached the pulp of the maxillary lateral incisor, the central incisor, and the first premolar at rates of 36%, 57%, and 0%, respectively. Maxillary canine impaction increases the risk of root resorption at adjacent teeth (incisors and first premolars). Physical proximity (≤1 mm) between the impacted canine and an adjacent root is the most important predictor for root resorption, and this characteristic is largely similar in Chinese patients to that in white people (12).

A Brazilian study (28) concluded that root resorption of adjacent teeth is present in most cases of canine impaction, mostly affecting the adjacent lateral incisors to a mild degree. Another study (29) associates severe incisor root resorption with female sex, enlarged dental follicles, a greater degree of canine displacement, and normal lateral incisors.

Regarding the size of canine dental follicle, no significant correlation was found between follicle width and the variables gender, impaction side, and MIC location. It could not be confirmed that increased dental follicle width of the MICs exhibited more resorption risk for the adjacent lateral

incisors (30). A Brazilian study (28) concluded that a wide dental follicle of impacted canines was not associated with a higher incidence of external root resorption of adjacent teeth . The same idea was stated in a study hypothesizing that the dental follicle of impacted maxillary canines does not cause resorption of adjacent maxillary incisors (31).

CONCLUSIONS

From this review we can conclude that impaction of maxillary canines occurs twice as often in females than in males. The palatal displacement of impacted maxillary canines is more common than labial displacement; however, it seems to be more buccal impactions of canines in the Asian population.

The most common degree of root resorption is severe on all root levels and surfaces, especially apical 1/3. Pulpal involvement includes both central and lateral upper incisors. Increased dental follicle width of the maxillary impacted canines do not cause a higher risk of lateral incisor root resorption.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest and they received no specific funding regarding this scientific research.

CHITOSAN-GELATIN MICRO/NANOPARTICLES AS A CONTROLLED DELIVERYOF DEX-KETOPROFEN TROMETAMOLFOR TOPICAL APPLICATIONS IN WOUND CARE (Abstract): Progress in the nanotechnology field has led to the discovery of various drug delivery systems for biomedical applications in the last few decades. **Materials and methods:** Micro/nanoparticles (MPs) based on chitosan (CS) and gelatin (GEL), designed as a drug delivery system for biomedical applications, were prepared using a double cross-linking process within an emulsion-phase separation system. **Results:** The obtained MPs were characterized using scanning electron microscopy (SEM), which revealed diameters ranging from 0.467 to 4.596 µm. The swelling properties of the MPs were investigated in a neutral environment with a pH of 5.5. **Conclusions**: The applicability of the prepared materials was further evaluated for drug loading and *in vitro* delivery of Dexketoprofen trometamol (DEX), demonstrating excellent capacity, which recommends them for effective wound care, including postoperative wounds. **Keywords:** CHITOSAN, GELATIN, MICROPARTICLES, NANOPARTICLES, DOUBLE CROSSLINKING, REVERSE EMULSION, DEXKETOPROFEN TROMETAMOL, DRUG DELIVERY.

INTRODUCTION

Nanotechnology is utilized to design various particulate systems that serve as effective drug delivery supports for a range of biomedical applications due to their unique properties. Natural polymers, especially polysaccharides, are particularly advantageous for biomedical use because of their chemical structure, which impart essential qualities such as biocompatibility, non-toxicity, biodegradability, abundance, relatively low cost, and renewable nature (1, 2).

Among natural polysaccharides, CS is the most frequently used support material for polymeric particles. It is highly regarded for its exceptional properties, including biocompatibility, biodegradability, non-toxicity, mucoadhesion, and the presence of highly reactive amine groups. CS can be chemically modified to improve specific characteristics, such as solubility, mucoadhesion, and stability, thus expanding its potential applications in drug delivery (3).

Similar to CS, GEL is a biodegradable polymer that has attracted growing interest in recent years due to its diverse applications and favorable properties, such as biodegradability, biocompatibility, non-toxicity, and ease of cross linking and chemical modification (4, 5). As a natural and renewable substance, GEL is utilized in various fields, including bioengineering, pharmaceuticals, and the food industry (6, 7). It is derived from the partial hydrolysis of collagen, which is found in animal tissues such as bones, hides, and pigskin (8).

The diversity and effectiveness of CS, respectively gelatin-based particle systems for drug targeting and controlled drug release applications have been well-documented in the literature. Particles based on CS and/or GEL prepared via emulsification and crosslinking method, containing different bioactive molecules have been extensively recorded in the literature(9-13).Thus, GEL and CS particles represent a promising carrier system for controlled drug delivery technology.

The current study involves the preparation of MPs based on CS and GEL through a double crosslinking process using a water-in-oil emulsion. The MPs were characterized in terms of morphology, swelling behavior, and drug loading/release properties, which were controlled by adjusting synthesis parameters such as polymer concentration and the GEL/CS ratio. *Invitro* tests were conducted to demonstrate the MPs' capacity for drug loading and release of DEX. We can state that the prepared MPs can be used as support for post-surgical drug administration. Usually, acute wounds are associated with inflammation and in uncontrolled inflammation, proinflammatory macrophages and inflammatory mediators such as tumor necrosis factor α (TNF-α) and interleukin-1β (IL-1β) become overexpressed. As a result, acute wounds become chronic and difficult to heal, incurring additional costs to healthcare systems and especially decreasing the quality of life of affected patients (14). Therefore, a non-steroidal anti-inflammatory drug such as DEX can effectively contribute to the wound healing process and thus benefit both patients and healthcare system management.

MATERIALS AND METHODS

Materials

The following materials were used: low molecular weight Chitosan (CS, deacetylation degree 75-80%, Sigma Aldrich, Saint Louis, MO, USA), Gelatin (GEL, Sigma Aldrich, Saint Louis, MO, USA), Glutaraldehyde (GA, Sigma Aldrich, Saint Louis, MO, USA) –25% aqueous solution, sodium sulfate (Sigma Aldrich, Saint Louis, MO, USA), Acetone (Sigma Aldrich, Saint Louis, MO, USA), Hexane (Sigma Aldrich, Saint Louis, MO, USA), Dexketoprofen trometamol (DEX, Sigma Aldrich, Saint Louis, MO, USA), Tween 80 (Sigma Aldrich, Saint Louis, MO, USA), Span 80 (Sigma Aldrich, Saint Louis, MO, USA), Milli-Q ultrapure distilled water (DW, Merck).

Methods

GEL-CS Microparticles synthesis

The chosen method for MPs preparation involved a double crosslinking (ionic and covalent) technique using a water-in-oil emulsion (10, 11, 12). First, a CS solution was prepared by dissolving the polymer in

a 2% (w/w) aqueous acetic acid solution. Second, GEL was dissolved in double distilled water at 40°C. According to specific polymer ratios, the CS and GEL solutions were mixed, and Tween 80 was added to the solution (1%, w/w) and stirred vigorously for 10 minutes. Next, separately, the organic phase was prepared by mixing a 1% (w/w) Span 80 solution in toluene. The MPs were obtained by gradually adding the polymer solution to the organic phase (water/oil ratio 1/4) while homogenizing with an UltraTurrax at 20.000 rpm for 10 minutes, leading to emulsion formation. Subsequently, freshly prepared crosslinker aqueous solutions, namely sodium sulfate (10%), were added at a rate of 1 mL/min with continuous stirring for another 10 minutes. Afterward, the emulsion was transferred to a round-bottom flask and mechanically stirred at 1000 rpm. Subsequently, 10 mL of a saturated GA solution in toluene was added, and the mixture was stirred for another 1 hour. The MPs were separated by centrifugation at 10.000 rpm and repeatedly washed with acetone and water to remove unreacted compounds. After washing with hexane, the obtained MPs were dried at room temperature.

Techniques used for characterization

MPs morphology was investigated by SEM technique. SEM micrographs were recorded with a HITACHI SU 1510 (Hitachi SU-1510, Hitachi Company, Japan) Scanning Electron Microscope, MPs were fixed on an Aluminum stub and coated with a 7 nm thick gold layer using a Cressington 108 device before observation.

MPs swelling behavior in aqueous media

MPs swelling characteristics in the aqueous environment were evaluated by the gravimetric method using a buffer solution (pH 5.5) (Phosphate Buffer Solution, PBS).

0.030g of MPs were immersed in a 2 mL Eppendorf tube containing 1 mL of PBS. The suspensions were monitored and maintained at room temperature under mechanical stirring (100 rpm) for 24 hours when equilibrium swelling was attained. MPs suspensions were ultra-centrifuged (12.000 rpm), withdrawn from the buffer solutions, and weighed at specified time intervals, respectively immediately replaced with an equivalent volume of fresh buffer. The maximum swelling degree was determined with equation (Eq.) (1):

$$Q\% = \frac{w_s - w_0}{w_0} \times 100 \quad \textbf{(1)}$$

where:

w_s- the weight of swollen CPH;

w_0- the weight of dry CPH.

MPs drug loading capacity

DEX is the tromethamine salt of S-(+)-2-(3-benzoylphenyl) propionic acid, an analgesic, antipyretic, and anti-inflammatory drug that belongs to the class of non-steroidal anti-inflammatory drugs (NSAIDs)(15). DEX was utilized as a model drug for loading into the microparticle (MPs) drug delivery system. The loading process of DEX was conducted via a diffusional mechanism. Specifically, MPs (0.030g) were suspended in 1 mL of an aqueous DEX solution (c = 20 mg/mL, dissolved in PBS pH=5.5) and dispersed by sonication for 10 minutes. These suspensions were maintained at room temperature with gentle mechanical stirring for 72 hours. After, MPs samples were centrifuged (15,000 rpm, 5 min). The amount of DEX encapsulated in the MPs was quantified by determining the drug content in the supernatant, calculated using Eq. (2) derived from a previously prepared calibration curve.

$$y = 3.9395x + 0.0092; \; R^2 = 0.9917 \quad \textbf{(2)}$$

Drug encapsulation efficiency (DEE) represents the quantity of added drug (%) that is encapsulated in the formulation. The DEE of LEV from CPH was calculated with Eq. (3). The DEX entrapment efficiency of MPs was determined with Eq. (4).

$$\mathbf{DEE} = \frac{\text{Actual drug (LEV) content loaded in CPH}}{\text{Theoretical drug content (LEV)}} \times 100 \quad \mathbf{(3)}$$

$$\mathbf{Entrapment\ efficiency} = \frac{\text{The total amount of LEV} - \text{Amount of LEV from supernatant}}{\text{Total amount of LEV}} \quad \mathbf{(4)}$$

All tests were accomplished with a spectrophotometer UV-VIS Nano Drop ND-1000. DEX-loaded MPs were freeze-dried.

In vitro DEX release from MPs

To assess the *invitro* drug release properties, the release of DEX-loaded MPs was conducted in PBS with a pH of 5.5, ensuring a slower release rate of the drug. The DEX release process involved immersing the DEX-loaded MPs in a 2 mL Eppendorf tube containing 1 mL of PBS. The suspensions were maintained at 37°C with continuous gentle stirring at 50 rpm. At predetermined time intervals, the suspensions were ultracentrifuged at 12.000 rpm, and the amount of released DEX was quantified using UV-VIS spectrometry at 258 nm. Each determination was performed in triplicate, and the results were averaged.

RESULTS

The selected method for the MPs preparation was a double crosslinking (ionic and covalent) technique within a water-in-oil emulsion. The method advantage is due to a reduced amount of covalent crosslinker required, which subsequently decreases the final product's toxicity. The fundamental principle of this process involves forming an interconnected/interpenetrated network initially through predominantly ionic crosslinking, followed by a covalent crosslinking step. The experimental parameters used for the preparation of the MPs are detailed in first table.

TABLE I.
MPs Preparation parameters

Sample code	% GEL	% CS	Concentration (%)	Water/Oil ratio
M1	10	90	0.8	1/4
M2	30	70	0.8	1/4
M3	50	50	0.8	1/4
M4	70	30	0.8	1/4
M5	10	90	1.2	1/4
M6	30	70	1.2	1/4
M7	50	50	1.2	1/4
M8	70	30	1.2	1/4

The parameters taken into consideration for the preparation process were total initial concentration and the GEL/CS ratio. The initial water/oil phase ratio, surfactant concentration, and ionic and GA content in the aqueous/organic phase were kept constant

throughout the study.

The morphology of the prepared microparticulate systems was examined using SEM (fig. 1). The results indicate that the MPs exhibit a spherical shape, are well-individualized, generally possess a micron diameter, and demonstrate a dimensional polydispersity. Moreover, two primary particle populations were observed: the first consisted of particles in the micron range, characterized by rough surfaces and an approximately spherical shape, while the second population comprised submicron particles with a distinct spherical shape and smooth surfaces. Also, the images confirm the obtaining of MPs with variable diameters which ranged between 0.550 – 1.36 µm for M1-M4, respectively 0.467 – 4.596 µm for M4-M8. The adapted emulsion double crosslinking procedure effectively produces clear particulate systems with relatively low dimensional dispersity, as evidenced by the SEM micrographs.

To further understand the interaction between the MPs and the aqueous environment, swelling studies were conducted in a neutral medium (pH = 5.5) using a gravimetric method. The water swelling behavior provides insights into the interactions between double-crosslinked MPs CS-GEL and the selected environment, as well as its suitability for the drug loading and release processes. Figure 2 displays the kinetic data for all samples, while table II presents the maximum swelling degree values obtained. The results revealed that the maximum swelling degree for the M1-M4 samples ranged from 706% to 787%, and for the M5-M8 samples, it ranged from 681% to 788%. The swelling kinetics, as shown in Figure 2, indicate that an equilibrium phase is established, demonstrating the good stability of the particulate formulations. Also, was observed that when the ratio between GEL and CS is in favor of GEL the water uptake increased, demonstrating good water-CS interactions, most likely favored by the hydrophilic GEL.

DISCUSSION

Considering the swelling results which demonstrate that MPs presented a high ability to swell, DEX was loaded in neutral conditions ensuring the encapsulation of a higher amount of drug. The ability of MPs to encapsulate drugs was analyzed using DEX as a model drug. The DEX content in the supernatant was analyzed using UV-VIS spectrophotometry (at 258 nm wavelength) based on an established calibration curve. Table III presents the DEX loaded MPs amounts and loading efficiency. MPs were able to entrap DEX between 0.46 – 0.48 mg drug/mg particles. Therefore, the DEX loading efficiencies values calculated with Eq. 4 were between 98.0 – 99.0%, showing a high capacity of the MPs as support for the biologically active compound.

The DEX release capacity of MPs was analyzed by the diffusion method in PBS pH = 5.5 at 37°C. The released DEX for all samples is presented in Table IV and the kinetic data are displayed in Figure 3 a) and b). The results showed a fast release phase which is reached within the initial 6 hours followed by a slower phase (characterized by a slow release) until 72 hours. The sustained release of DEX can be explained by the fact that the released drug was adsorbed in the MPs network due to excellent hydrophilicity of the polymer network which it seems that it is maintained also after the crosslinking procedures. The maximum released amount of DEX varied between 0.146 and 0.301 DEX mg/mg MPs (Table IV, Figure 3a). Also, the release efficiency of DEX for all MPs samples, values between 30 and 65% were obtained (tab. IV, fig. 3b), the highest efficiency being noticed for the sample M4 and M8 which has been shown also a high-swelling degree.

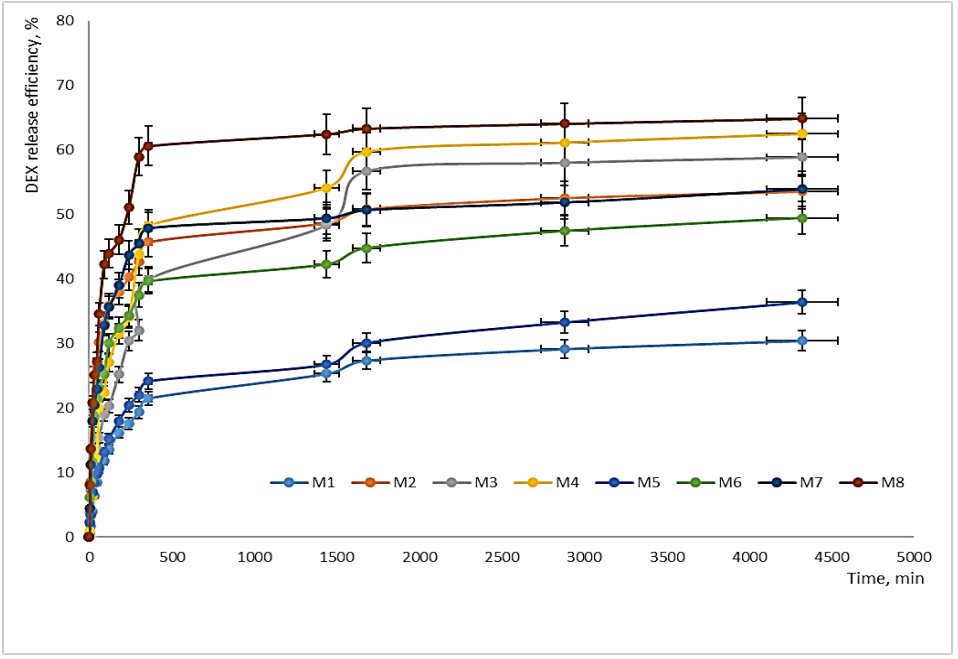
a)



b)

Fig. 3. MPs ability to *in vitro* release DEX: a) DEX mg/mg MPs;
b) DEX releasing Efficiency, %

The results of release kinetics were analyzed also based on the Korsmeyer-Peppas mathematical model. From the linear plotting of DEX release data (figs. 4a, 4b), it can be observed that (n) is smaller than 1, indicating that the drug release mechanism follows a Non-Fickian transport (16, 17).

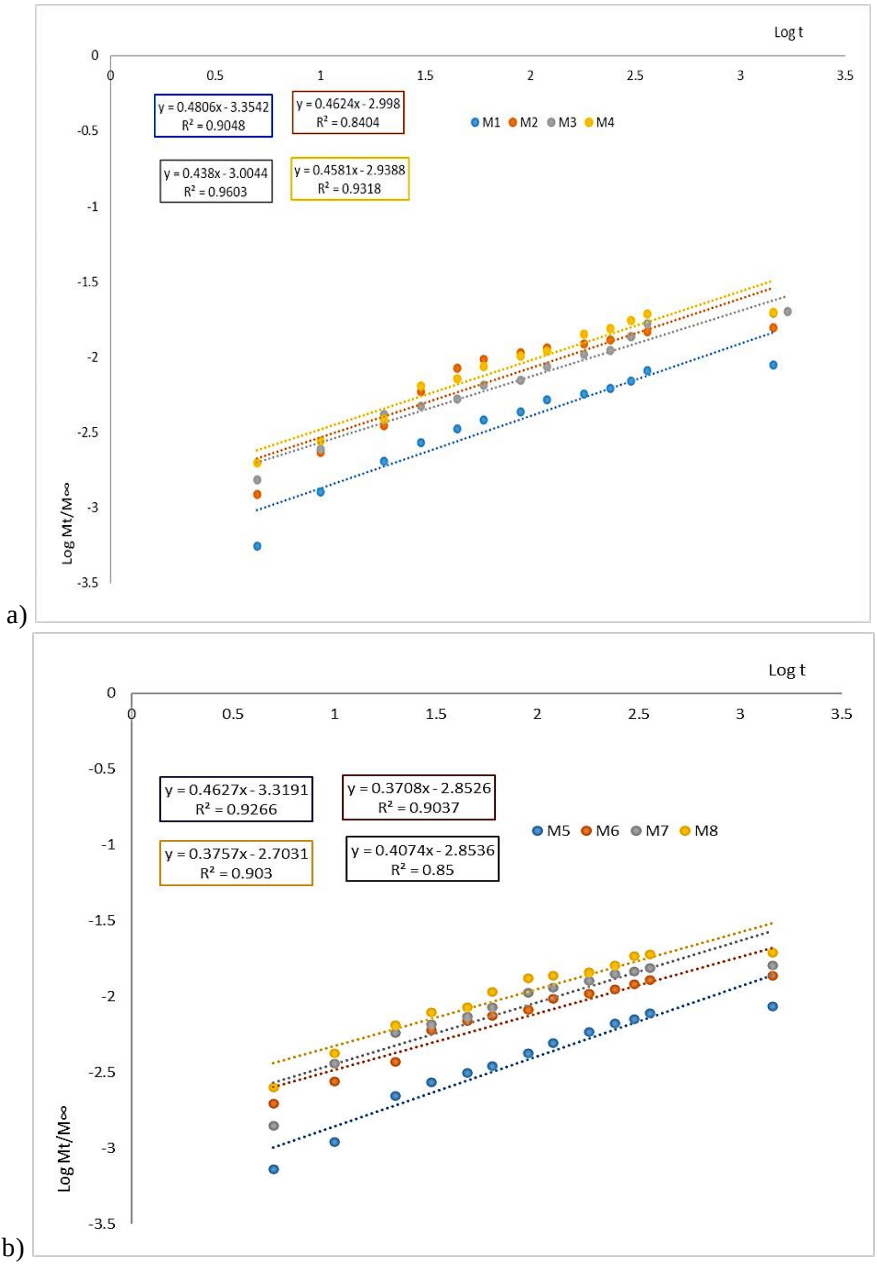


Fig. 4. Korsmeyer-Peppas model for a) M1-M4 samples; b) M5-M8 samples

The diffusional exponent (n) values, determined using the Korsmeyer-Peppas model, ranged from 0.37 to 0.48. In the case of M1 - M4 samples the diffusional exponent (n) values were between 0.43 and 0.48. It can be observed that the values of the exponent n, which characterize the release mechanism, are notably close to 0.5 ($0.5 < n < 1.0$). The results suggest that the transport/release mechanism is predominantly governed by diffusion. Moreover, in the case of samples M5 – M8 was observed that the values of the exponent n are lower than 0.5. This indicates an anomalous transport, which combines both diffusion and swelling mechanisms of the analyzed samples (18).

CONCLUSIONS

The present work demonstrates the amenability of CS-GEL for the preparation of particulate systems through a double cross-linking process into a reverse emulsion. SEM micrographs revealed two primary particle populations: the first consisted of micron-sized particles with rough surfaces and an approximately spherical shape, while the second population comprised submicron particles with a distinct spherical shape and smooth surfaces. Additionally, the images confirmed the formation of MPs with variable diameters ranging from 0.550 to 1.36 μm for M1-M4, and from 0.467 to 4.596 μm for M4-M8. MPs behavior in aqueous media with pH = 5.5 was studied, demonstrating a higher water retention capacity.

The MPs water uptake properties are significantly influenced by polymer concentration and CS-GEL ratio employed in the preparation stage, and they are correlated with the particle size. The drug loading and release capacity of MPs, tested using DEX, showed a good diffusional loading capacity, up to 0.5 mg of DEX per mg of MPs in a neutral environment. A rapid drug release was observed within the first 6 hours, followed by a slower phase, characterized by a constant release, up to 72 hours. Drug release kinetics analysis demonstrated that the drug transport/release mechanism is predominantly diffusional.

The obtained result confirms that CS-GEL-based MPs are a promising carrier system for controlled drug delivery for biomedical applications, including topical application of DEX to support the normal wound healing process, with all the advantages of prolonging the time of action and minimizing the specific side effects of NSAIDs, which will significantly improve patient compliance with this type of treatment.

STUDY ON EDENTULISM COMPLICATIONS IN PATIENTS ELIGIBLE FOR HYBRID PROSTHETIC TREATMENT. A CROSS-SECTIONAL STUDY (Abstract). Aims of study. Patients with extended partial edentulism or complete edentulism, eligible for hybrid prosthetic solutions, are frequently affected by edentulism complications. The **aim** of our study was to find out the distribution of the edentulism complications that can impair biomechanical stability of the prosthetic treatment in patients eligible for hybrid prostheses. **Materials and methods:** A descriptive cross sectional, retrospective study, was conducted in Clinical Learning Base of Faculty of Dental Medicine, "Grigore T. Popa" University of Medicine and Pharmacy Iasi. 150 subjects with partial extended or complete edentulism (mean age 61,54 +/- 8,99 yrs.), eligible for hybrid prosthetic therapy were evaluated. Patients were divided in two groups: Group A (n=96): patients with partial reduced or extended edentulism that were eligible to hybrid prosthetic therapy, retained by fixed teeth-supported prosthetic restoration; Group B (H-PFR/IP) (n=54): patients with total or subtotal edentulism that were eligible to implant-supported hybrid prosthetic therapy, retained by fixed implant-supported prosthetic restorations. Data were collected regarding the patients' variables and edentulism complications. The need for therapeutic interventions in the pro-prosthetic and pro-implant stage was evaluated. **Results:** Significantly higher percentage of edentulous arches in Group B (90.9%) experienced severe bone resorption compared to Group A (45.6%). Temporo-mandibular joint pathology was notably more prevalent in Group B (94.4%) than in Group A (51.0%) ($p < 0.001$**). Group B had a higher prevalence of muscular disorders (77.8%) compared to Group A (32.3%) ($p < 0.001$**). Mandibular-cranial misalignments were significantly more common in Group B (88.9%) than in Group A (52.1%) ($p < 0.001$**). Temporomandibular disorders were significantly more prevalent higher in patients from Group B (94.4%) when compared to Group A (54.2%) ($p < 0.001$**). **Conclusions**: Patients eligible for hybrid prostheses consisting of removable dentures retained by fixed implant-supported bridges have significantly higher percentages of complications and need for pro-implant therapeutic interventions than patients eligible for removable dentures retained by fixed implant-supported bridges. **Keywords:** EDENTULISM, COMPLICATIONS, HYBRID PROSTHESIS.

Edentulism is a global concern, with projections indicating an increasing need for complete dentures and removable dentures in the future. Complete edentulism is the final result of a multifactorial process involving both biological and patient-

related factors. Among older adults, an increase in the number of comorbidities was found to be predictive of the onset of edentulism, with this pattern of association observed consistently across two longitudinal study periods. As the number of comorbidities rises, older adults may face a greater likelihood of tooth loss over time (1). Nonregular dental attenders were more likely than regular dental attenders to become edentulous, while smokers were more likely than non-smokers to become edentulous (2). Patients who are completely edentulous were found to be at higher risk for several health issues, including poor nutrition, coronary artery plaque formation, smoking, diabetes, rheumatoid arthritis, and various cancers (3). An increased number of missing teeth to be replaced, increases the likelihood of a removable restoration (4). Modern treatments based on combination of teeth-supported fixed bridges and hybrid removable dentures as well as implant-supported hybrid dentures helps both in minimizing the loss of residual alveolar ridges, rehabilitation of the masticatory and aesthetic functions, and the social reintegration (5).

Designing a hybrid prosthesis requires a thoughtful and systematic approach, grounded in strong clinical and technological expertise. The treatment of partially extended edentulism demands a comprehensive understanding of the case, including clinical indications and elements of maintenance, support, and stability (6). The treatment plan must take into account the aesthetic aspects, the remaining teeth on the dental arches and the tissues of the prosthetic field (7). The extraoral clinical examination reveals aspects that individualize the prosthetic treatment plan by identifying pre-existing conditions such as muscle dysfunction and temporomandibular joint (TMJ) pathology, which may restrict mouth opening and cause lateral deviation. It is crucial to assess the origin of these disorders, their etiology, and the extent of morphological and functional impairment (8). A successful hybrid prosthetic treatment requires effective approach of complications of partial and complete edentulism in the pre-prosthetic, pro-prosthetic and pro-implant stages. While residual ridge resorption remains the primary intraoral complication of edentulism, the planning of the treatment of the edentulous patient candidate to hybrid prosthetic treatment must approach complications such as need for grafting of the severe resorbed alveolar bone, and occlusal rehabilitation and rehabilitation of the cranio-mandibular relationships (5). To improve planning of the treatment of the edentulous patients in the pre- and pro-prosthetic stages, as well as in the pro-implant stages, clinical-biological indices (systemic status, dental support, periodontal support, mucosal support, alveolar bone support, occlusion, cranio-mandibular relationships) must be assessed (5). Management of the full and partially edentulous arch requires also a thorough understanding of the vertical and horizontal restorative space needed for various types of hybrid prostheses The restorative space specific for each type of hybrid restoration should be carefully considered during treatment planning to avoid lack of stability, aesthetics compromise, and inadequate contours of the future denture. For patient candidate to implant-supported hybrid prosthetic treatment, the minimum vertical space needed is as follows: fixed screw-retained (implant level): 4-5 mm; fixed screw-retained (abutment level): 7.5 mm; bar overdenture: 11 mm; fixed screw-retained hybrid: 15 mm. Regarding horizontal space, calculations must

be addressed to the discrepancy between implant and tooth positions (9). In cases of patients with complete edentulism, the physiological mandibular position must be established before proceeding with immediate loading. The use of interim removable prostheses for a few weeks can be beneficial to test the new occlusion in centric relation and to validate the prosthetic plan. Once the correct intermaxillary relationships are achieved, transferring them from provisional to final prostheses can be challenging, as impressions or scans of edentulous arches lack reference points for intermaxillary records. Anthropometric indices may be used to improve aesthetic outcome, due to reproducible results related to perioral and overall facial morphology as well as the occlusal vertical dimension (10).

Expert system-based applications allow for the integration of data from medical history, along with information gathered from clinical and paraclinical examinations, to initially evaluate the parameters of the prosthetic field. Following the pre-prosthetic, pre-implant, and pro-implant stages, as well as after completing temporary prosthetics, these applications conduct a secondary evaluation before the final prosthetic treatment to compare the prosthetic field indices recorded during the initial and secondary evaluations (11). The software applications and expert systems utilized for assessing mucosal and osseous support parameters, as well as for planning the surgical implant stage, rely on data derived from CBCT images. Applications based on CBCT image processing have demonstrated significant value in preoperative diagnostics and the planning of techniques for implant site rehabilitation, including the dental implant insertion phase (12-15). Digital workflow allows for the adjustment of the vertical dimension of occlusion, while ensuring excellent adaptation of the prosthesis to the soft tissues, and decreases the number of sessions required to install the definitive implant-supported hybrid prosthesis (16-18).

The aim of our study was to find out the distribution of the edentulism complications that can impair biomechanical stability of the prosthetic treatment in patients eligible for hybrid prostheses.

MATERIALS AND METHODS

Study groups included a total number of 150 subjects with partial extended or complete edentulism (gender: 82 males, 68 females; mean age 61.54 +/- 8.99 yrs.), selected from Clinical Learning Base of Faculty of Dental Medicine, "Grigore T. Popa" University of Medicine and Pharmacy Iasi, Romania, between 30.02.2023 and 30.05.2024 (tab. I). All patients were eligible for hybrid prosthetic therapy. Patients were divided in two groups: Group A (H-PFR/T) (n=96): patients with partial reduced or extended edentulism that were eligible to hybrid prosthetic therapy (maxillary and/or mandibular hybrid prosthesis using a substructure of metal covered by acrylic teeth, retained by fixed teeth-supported prosthetic restorations); Group B (H-PFR/IP) (n=54): patients with total or subtotal edentulism that were eligible to implant-supported hybrid prosthetic therapy (maxillary and/or mandibular hybrid prosthesis using a substructure of metal covered by porcelain fused to metal teeth, retained by fixed implant-supported prosthetic restorations).

Clinical and paraclinical evaluations were performed for each patient. Data were collected regarding the type of edentulism and Kennedy class, number of missing teeth, absence or presence of malocclusion, temporo-mandibular joint pathology, mus-

cular disorders, status of the cranial-mandibular relationships. Each patient was diagnosed for the presence or absence of the stomatognathic system disorders (TMD- temporo-mandibular disorders). The same methodology, clinical procedures, and evaluation criteria were used for patients in both study groups.

TABLE I.

Socio-demographic parameters of patients eligible to hybrid prosthetic treatment

		n	%
Gender	F	68	45.3
	M	82	54.7
Age groups	41-50	13	8.7
	51-60	50	33.3
	61-70	60	40.0
	71-80	27	18.0
Type of hybrid prosthesis	H-PFR	96	64.0
	H-PFR/IP	54	36.0
Total		150	100.0

Statistical analysis. Statistical analyses were conducted using *Microsoft Excel* and *SPSS version 29.0*. For qualitative data (where values represent categories), frequency distributions were created. The determined values were graphically represented using histograms (in various forms), and for qualitative variables, Pie Charts were also used. For numerical data, we calculated descriptive statistics parameters, including the mean, standard error of the mean, standard deviation, and minimum, maximum, and median values. The t-Student test was used for comparisons between samples, after verifying that the value distribution follows a normal distribution using the Kolmogorov-Smirnov goodness-of-fit test. The threshold of statistical significance was $p<0.05$.

RESULTS

Table II compares features and complications of edentulism in patients eligible for hybrid prosthetic therapy between Group A (H-PFR/D) and Group B (PFR/IP). Table III exposes features and edentulism complications related to the maxillary and mandibular arches. Percentages of patients eligible for hybrid prosthetic treatments were higher for males (54,7%) when compared with females (45,3%), with similar proportions intra-groups ($p=0.870$). In group A percentages of patients were highest in age group 51-60 yrs. (42,7%), followed by age group 61-70 yrs. (40,6%). In group B percentages of patients were highest in age group 61-70 yrs. (38,9%), followed by age group 71-80 yrs. (44,4%). Highly significant differences regarding the distribution of patients according to age were found between groups ($p < 0.001$**). Group B had a significantly higher percentage of patients with mandibular edentulism (33.3%) compared to Group A (17.7%), while higher percentage (44,4%) of patients from Group B had maxillary edentulism when compared to patients from Group A (29,2%). Additionally, maxillary and mandibular combined edentulism was more prevalent in Group A (53.1%) than in Group B (22.2%), with a p-value of 0.001**.

Group A predominantly consisted of patients with partial extended edentulism (88.5%), whereas Group B had a higher prevalence of total edentulism (83.3%). The difference was statistically significant with a p-value of <0.001**. Regarding the distribution of the severe alveolar bone resorption, a significantly higher percentage of patients in Group B (88.9%) experienced advanced bone resorption compared to Group A (49.0%), with a p-value of <0.001**. All patients in Group B (100%) exhibited malocclusion, compared to 82.3% in Group A, with a significant difference (p-value of 0.001**). TMJ pathology was notably more prevalent in Group B (94.4%) than in Group A (51.0%), reflected by a p-value of <0.001**. Group B had a higher prevalence of muscular disorders (77.8%) compared to Group A (32.3%), with a significant p-value of <0.001**. Mandibular-cranial misalignments were significantly more common in Group B (88.9%) than in Group A (52.1%), with a p-value of <0.001**. Temporomandibular Disorders were significantly more prevalent higher in patients from Group B (94.4%) when compared to Group A (54.2%), with a p-value of <0.001**. No significant statistical difference was found in the incidence of dishomeostasis between the groups (p-value = 0.102). The comparison of parameters and edentulism complications related to the edentulous maxillary and mandibular arches, between Group A (H-PFR/T) and Group B (H-PFR/IP), ob-

served highly significant statistical differences ($p<0.001$**) between the groups in the distribution according to age, edentulism type, and presence of moderate/advanced alveolar bone resorption. According to age, Group B had a notably higher percentage of edentulous arches in the 71-80 age group (45.5%) compared to Group A (2.0%), while Group A had a higher representation in the 51-60 and 61-70 age groups. According to the edentulism type, Group A predominantly consisted of arches with extended partial edentulism (88.4%), while Group B had a much higher proportion of total edentulism (72.7%). Significantly higher percentage of edentulous arches in Group B (90.9%) experienced severe bone resorption compared to Group A (45.6%).

DISCUSSION

The objectives of our study were to investigate edentulism complications that can impair biomechanical stability of the future hybrid prosthetic treatment.

In a comparative analysis between patients from Group A (hybrid removable prostheses retained by fixed teeth-supported bridges) and Group B (hybrid removable prostheses retained by implant-supported bridges), it was observed that Group B exhibited a notably higher prevalence of several edentulism complications compared to Group A. Specifically, a substantially larger proportion of patients in Group B experienced medium to advanced alveolar bone resorption. Additionally, every patient in Group B showed signs of malocclusion, whereas a smaller portion of Group A was affected. TMJ pathology was markedly more common in Group B, with nearly all patients being affected, in contrast to a significantly lower proportion in Group A. Similarly, muscular disorders were more frequently observed in Group B, where the prevalence was more than double that seen in Group A. Mandibular-cranial misalignments were also more prevalent in Group B, with a significant difference when compared to Group A. Lastly, Temporomandibular Disorders were observed much more frequently in Group B, with the prevalence being almost twice as high as in Group A. The statistical significance of these findings underscores the considerable disparity in the health profiles of the two groups. Number and position of missing teeth, occlusal relationships, periodontal health of the remaining teeth, and the movement pattern or size of the tongue are considered local factors, while systemic factors include neuromuscular control, age, psychological status, and overall health resilience (19). Oral cavity and temporomandibular joint (TMJ), a mechanically demanding and biochemically dynamic environment, requires therapeutic approaches that can not only restore joint functionality but also adapt to ongoing changes within the joint (20). While multifactorial theory was considered to explain TMJ disorders, various treatment approaches, should be aimed to resolve possible etiology from different aspects (21). Prosthetics specialists must design a comprehensive plan of definitive hybrid prosthetic treatment, while considering the loss of occlusal relationship and adverse effects on the stomatognathic system in patients with extended partial edentulism or complete edentulism. Temporomandibular joint, as a significant component of this system, may also

be affected by edentulism in the process of supporting mandibular movement. Considering the interrelationship between the components of the stomatognathic system, the impairment of one component often leads to the damage of the others, or at least some of them, while mandibular-cranial misalignment exacerbates the severity of dysfunction, making mandibular recovery more challenging and sometimes limiting therapeutic options (22).

CONCLUSIONS

Most edentulous patients eligible have edentulism complications that will impair biomechanical stability of the future hybrid prosthetic treatments. Patients eligible for hybrid prostheses consisting of removable dentures retained by fixed implant-supported bridges have significantly higher percentages of complications (medium/advanced alveolar bone resorptions, temporo-mandibular disorders) than patients eligible for removable dentures retained by fixed implant-supported bridges.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

THE DECISION-MAKING PROCESS BEHIND REMOVABLE PROSTHESIS: A THERAPEUTIC AND DESIGN PERSPECTIVE (Abstract): The prosthodontics revolution, which reinstated oral function, enhanced aesthetics, and improved patient satisfaction, contains removable dentures as one of its vital parts. **Materials and methods:** This study examined a group of patients who sought prosthetic treatment to determine the factors that influence partially extended dentition treatment decisions, treatment solutions, and removable prosthesis design. **Results:** A retrospective study was carried out, including 546 patients who addressed the Dental Faculty in Iasi's Department of Partial Dentures. According to this study, the palatal plate was the most popular maxillary major connection, followed by the U-shaped connector. This result may assist in assessing the quality of removable partial dentures provided to patients. **Conclusions**: Future advancements in digital dentistry and 3D printing may facilitate the creation of customized connection designs adapted to individual requirements, while heightened understanding of gender-specific tendencies might enhance treatment outcomes. **Keywords:** REMOVABLE DENTURE, MAIN CONNECTOR, PROSTHETIC TREATMENT, ORAL HEALTH.

INTRODUCTION

Removable dentures have been an integral part of the prosthodontics revolution, which has restored oral function, improved aesthetics, and increased patient happiness. Dentures, both full and partial, can replace natural teeth when they are lost as a result of disease, decay, or accident. These devices enhance the patient's psychological well-being by restoring chewing efficiency, communication, and facial attractiveness. Clinical, functional, aesthetic, and patient-centered concerns are all part of the decision-making process when choosing a removable denture (1).

Both clinical requirements and aesthetic preferences should be considered before settling on a removable denture. Improving the patient's quality of life, restoring functioning, and preventing future oral degeneration are the key therapeutic aims. The level of tooth loss, the condition of the patient's remaining teeth and gums, and the patient's general oral health are all important considerations for clinicians. These evaluations determine the choice of the best removable denture treatment-full or partial -and the particular design elements needed to fulfil the patient's requirements (2, 3).

From a design perspective, the construction of removable prostheses must

balance functionality, comfort, and aesthetics. Modern prosthetic design considers not only the biological factors of tooth replacement but also the materials used, the fit and retention of the prosthesis, and its ability to harmonize with the patient's existing oral structures. Advances in dental materials and fabrication techniques have expanded the range of possibilities for creating durable and aesthetically pleasing removable prostheses (3).

These innovations enable more precise customization, ensuring that the prosthesis is tailored to each individual's unique oral environment (3, 4). An important aspect of the decision-making process is patient involvement. Today, a patient-centered approach is widely recognized as essential for achieving successful outcomes. Patients' expectations, preferences, and lifestyle factors must be integrated into the planning and design phases of removable dentures (5).

To ensure that patients are completely informed and satisfied with the final decision, it is vital to be able to talk honestly about the benefits, drawbacks, and possible difficulties of different prosthetic solutions. The consultation is the opportunity to address all of the patient's worries, including those about the prosthesis's look, its comfort while using it, and the amount of time it will take to adjust to it (6, 7).

Furthermore, clinicians must also consider the long-term success and maintenance of removable prostheses. The selection of materials and design features plays a crucial role in the longevity and stability of the prosthesis, while regular follow-up care is necessary to monitor any changes in the patient's oral health or adjustments needed for the dentures over time (5). The manufacturing process has been simplified with the incorporation of modern technologies like 3D printing and digital impressions, which allows for more precise fits and reduces patient pain during the adaption phase (8).

A removable prosthesis is often the result of a multi-factorial decision-making process that considers clinical requirements, patient preferences, and technological advancements in the field. When permanent treatments like implants or bridges are not an option owing to health, anatomy, or cost, removable prosthesis might be the most practical or affordable option for tooth replacement for many individuals. Because of its portability, affordability, and convenience of use, removable prostheses remain an important aspect of dentistry, even when fixed alternatives are available. This is especially true for patients who are either completely or partially missing teeth (9).

At the level of a group of patients who sought out prosthetic treatment, this study intends to assess the elements that impact the treatment decision for partially extended dentitions, as well as the impact of these factors on the treatment solution and the final design of removable prostheses.

MATERIALS AND METHODS

The proportion of Romanians 65 and older has been on the rise for some time now, mirroring a worldwide trend. Some forms of cancer, chronic kidney disease, Alzheimer's type dementia, hypertension, diabetes, chronic obstructive pulmonary disease, vascular accidents, and other chronic diseases are becoming more common as a result of these demographic shifts. Additionally, there is a correlation between one's dental health and their overall physical health, which influences treatment strategies, according to the research (10, 11).

Despite widely known statistics, our un-

derstanding of the unique requirements pertaining to the physical and dental health of patients over the age of 60 is still limited.

Consequently, improving the quality of life for older patients and providing them with more effective health care can be achieved by a comprehensive investigation of the relationship between overall physical health and oral condition (4).

The specifics of the prosthetic field are carefully examined to determine the best course of treatment, with an eye towards assessing the odonto-periodontal support, the muco-osseous support, and the presence of local, loco-regional, or systemic issues (12, 13). Reducing pressures on the supporting tissues and distributing forces over as large an area as feasible are ideal goals of the partial denture design (14).

In order to conduct this study, researchers analyzed and quantified clinical documents from patients who had professional prosthetic therapy at the Dental Faculty in Iasi's Department of Partial Dentures.

A number of factors were examined, including the design of different prosthetic structures, the ratio of current clinical-biological characteristics that impact treatment selection, and the therapies using removable partial dentures. The 873 people who sought out prosthetic therapy from 2004 to 2019 were part of the group investigated for these characteristics. After collecting all of the necessary data from various sources, including patient registration sheets, computer tomography, study casts, laboratory archives, and individual case presentations, a total of 546 patients were included in the final research.

This study was approved by the "Grigore T. Popa" University of Medicine and Pharmacy, Iasi's ethics committee (No. 9430/12.06.2020), and all participants were told that clinical and paraclinical data will be used in the study.

Inclusion criteria

Patients had to meet the following criteria in order to be included: they had to be 19 years old or older; all treatment information and protocols had to be included in the patient record; they had to be from a socially disadvantaged category and not be employed at the time; paraclinical examinations had to be done, including at least one radiological investigation (CT, MRI, or x-ray) and the initial cast study; specific laboratory data sheets had to be included, detailing all aspects of the removable dentures and how they were designed to provide stability and support.

Exclusion criteria

Patients who did not continue treatment after getting transitional dentures or who had incomplete treatment were not included in the study. Other exclusion criteria included incomplete specific laboratory data sheets, a lack of paraclinical investigations, and incomplete patient record data sheets.

The data was quantified, and statistical analysis and validation tests were run using descriptive statistics. Microsoft Access was used for parameter-specific analysis, and Excel and the database were used for statistical analysis. Parts of descriptive statistics as well as Pearson correlations were utilized in the statistical analysis.

RESULTS

From the analyzed database the following is a centralized distribution of the frequencies of local and loco-regional infections found in the patient group.

Gender characteristics

The men presented the following classification of conditions as seen in figure 1:

carious conditions- 37.6%, endodontic- 3.1%, periodontal- 41.6%, mucosal- 2.6%, underlying bone- 3.8%, loco-regional- 11.2%.

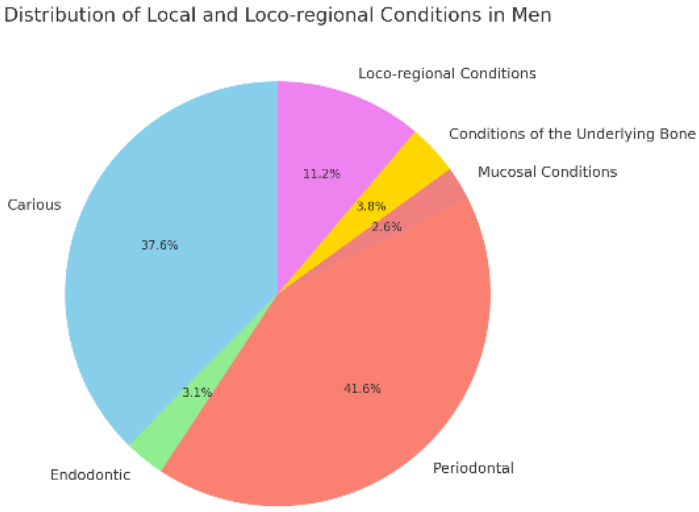

Fig. 1. Local and loco-regional conditions in men

The women presented the following classification of conditions as seen in figure 2: carious conditions - 34.3%, endodontic - 27.6%, periodontal - 16%, mucosal - 10.9%, underlying bone - 4.5%, loco-regional - 6.7%.

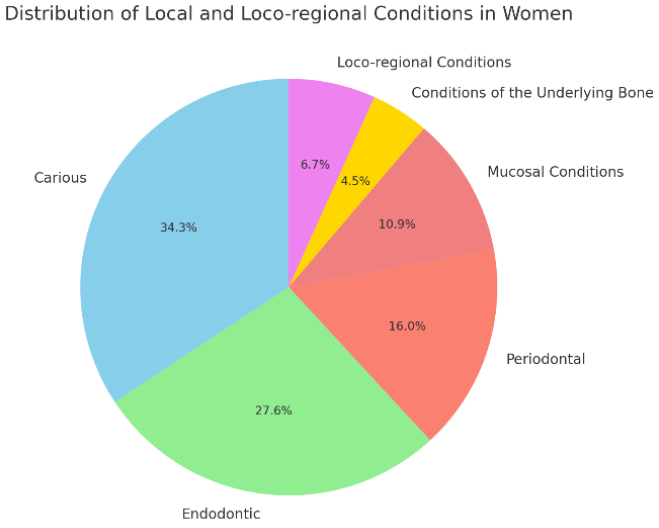

Fig. 2. Local and loco-regional conditions in women

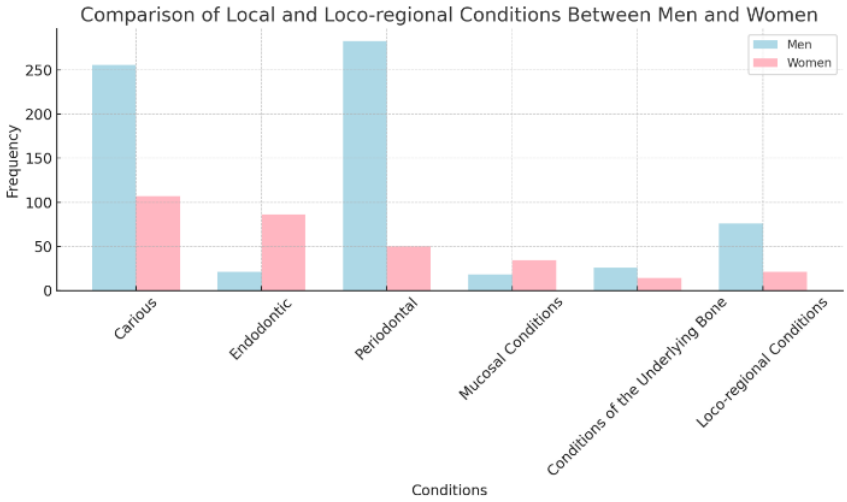

Fig. 3. Comparison between men and women of local and loco-regional conditions

Several factors could contribute to the observed differences in the prevalence of local and loco-regional conditions between men and women (fig. 3). These factors can be related to biological, behavioral, socio-economic, and healthcare access differences. Men tend to have worse outcomes in conditions like periodontal and carious diseases due to less frequent care and poorer oral hygiene, while women, despite seeking care more frequently, may exhibit higher rates of conditions like endodontic and mucosal diseases due to early detection and hormonal influences.

The frequency distributions for pre-existing general conditions were as follows in figure 4 for men: cardiac - 32.9%, renal - 7%, respiratory - 18.4%, metabolic - 10.5%, gastrointestinal - 12.1%, immunological - 0.4%, psychiatric - 6.3%, other conditions - 3.2%, good general health - 9.3%.

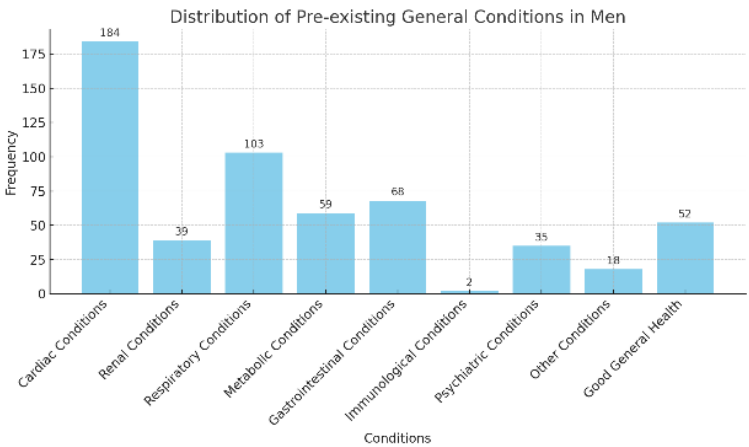

Fig. 4. Distribution of pre-existing general condition in men

Following the statistical analysis, women presented the following pre-existing general conditions: cardiac - 21.2%, renal - 1.7%, respiratory - 10.7%, metabolic - 18.1%, gastrointestinal - 16.4%, immunological - 5.6%, psychiatric - 7.9%, other conditions - 3.4%, good general health - 15% (fig. 5).

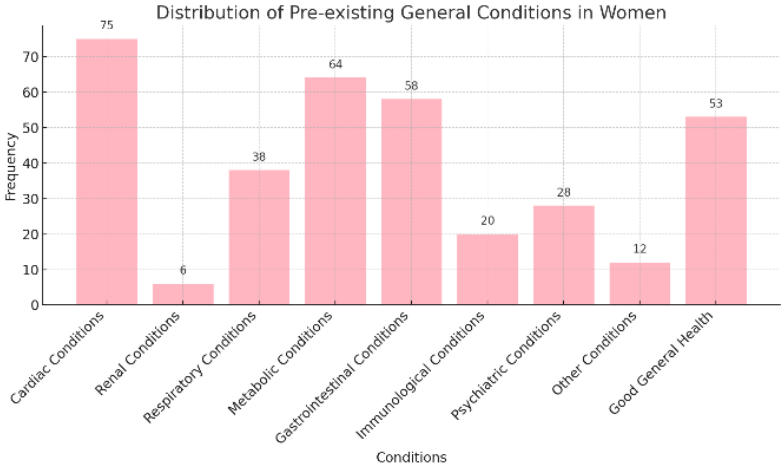

Fig. 5. Distribution of pre-existing general condition in women

The gender disparities in pre-existing conditions between men and women result from a combination of biological differences, lifestyle behaviors, societal norms, occupational exposure, and healthcare access. While men are more likely to experience cardiac and respiratory conditions, women show higher rates of metabolic and psychiatric conditions, likely due to a complex interplay of hormones, health-seeking behaviors, and social factors.

Main connectors

The frequency distributions for the types of connector designs used were as follows in figure 6:

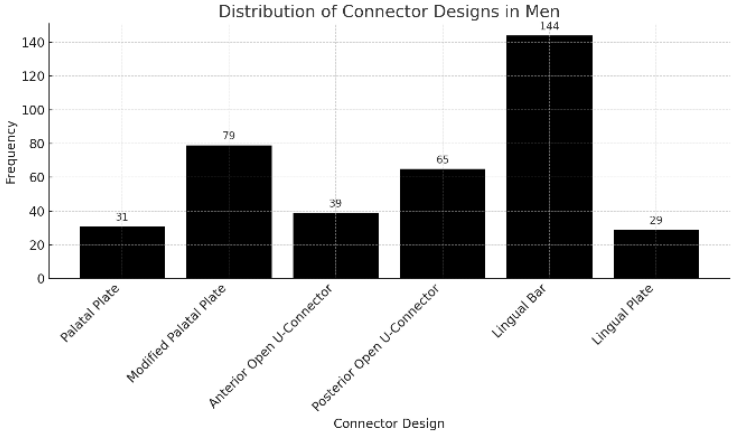

Fig. 6. Distribution of main connectors in men

The frequency distributions for the types of connector designs used in women were as follows in figure 7.

Analyzing the results, we can notice that there is a significant positive relationship between the design of the main connectors and the conditions of the present teeth (r = + 0.679 - correlation coefficient, N = 387, p < 0.0001) (tab. I). The positive value of the correlation coefficient indicates that as the values of one variable increase, the values of the other also increase. The coefficient r indicates a moderate association between the two variables.

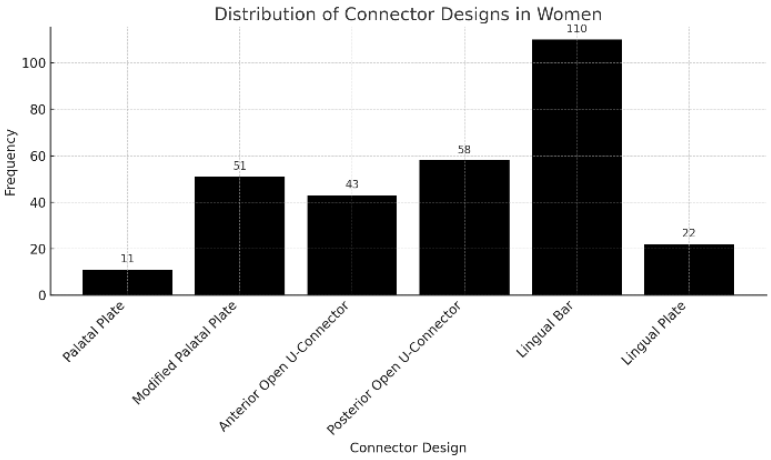

Fig. 7. Distribution of main connectors in women

TABLE I.

Correlations for men local conditions and connector design

		Design	Local condition
Connector design	Pearson Correlation	1	**.679****
	Sig. (2-tailed)		**.000**
	N	387	387
Local conditions	Pearson Correlation	.679**	1
	Sig. (2-tailed)	.000	
	N	387	560

**Correlation is significant at the 0.01 level (2-tailed).

And for women we also have a significant positive relationship between the design of the main connectors and the conditions of the present teeth (r = + 0.846 - correlation coefficient, N = 295, p < 0.0001) (tab. II). The positive value of the correlation coefficient indicates that as the values of one variable increase, the values of the other also increase. The coefficient r indicates a strong association between the two variables.

We also have a significant positive relationship between the design of the main connectors and pre-existing general condi-

tions (r = + 0.838 - correlation coefficient, N = 326, p < 0.0001) in men (fig. 8). The positive value of the correlation coefficient indicates that as the values of one variable increase, the values of the other also increase. The coefficient r indicates a strong association between the two variables.

And for women exist also a significant positive relationship between the design of the main connectors and pre-existing general conditions (r = + 0.846 - correlation coefficient, N = 295, p < 0.0001) (fig. 9). The positive value of the correlation coefficient shows that as the values of one variable increase, the values of the other also increase. The r coefficient indicates a strong association between the two variables.

TABLE II.

Correlations for women local conditions and connector design

		Design	Local conditions
Design	Pearson Correlation	1	**.846****
	Sig. (2-tailed)		**.000**
	N	295	295
Local conditions	Pearson Correlation	.846**	1
	Sig. (2-tailed)	.000	
	N	295	312

**. Correlation is significant at the 0.01 level (2-tailed).

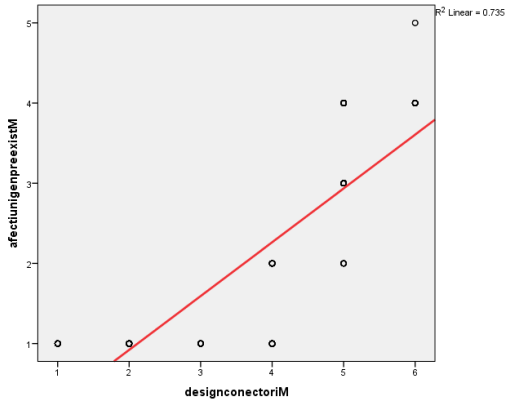

Fig. 8. Correlation between general conditions and main connectors in men.

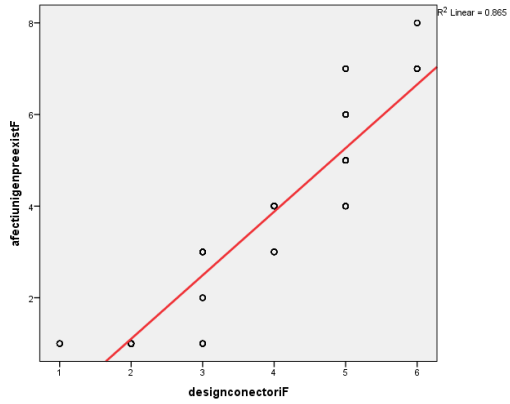

Fig. 9. Correlation between general conditions and main connectors in women.

DISCUSSION

Despite the inherent limitations, the present study had several strengths. First, the oral health status of the participants was classified based on multiple factors - local, loco-regional, and also the effect of general conditions, depending on the use of removable dental prostheses - specifically referring to types of connectors.

Based on this grouping scheme, a de-

tailed analytical and descriptive statistical analysis was conducted. Furthermore, the data in this study were collected by specialists, whereas previous studies relied on self-reported data. According to the results of this study, the palatal plate was the most dominant maxillary major connector, followed by the U-shaped connector.

The U-shaped major connector was used less frequently, in line with previous findings (15), possibly due to its mechanical deficiency and tendency to bend during handling or mastication (16,17), contrary to the results of Owall and Taylor (18), who found that the U-shaped major connector was used more (55.2%) than other maxillary major connectors.

Based on the results of the present study, the use of the lingual plate (21.2% and 16.2%) was significantly higher than that of the lingual bar. This is more likely due to the strength requirements for Kennedy Class I, which necessitates stability and indirect retention.

In the future, more personalized prosthetic treatments could be developed by considering patient-specific factors such as gender, lifestyle, and anatomical differences. Advances in digital dentistry and 3D printing may lead to customized connector designs tailored to individual needs. Further research could explore how cultural and regional preferences influence design choices.

Increased awareness of gender-specific trends may improve treatment outcomes. Lastly, integrating patient feedback into design development could enhance both function and comfort.

CONCLUSIONS

The results of this study might be helpful for evaluating the standard of removable partial dentures given to patients.

For training and educational purposes, it also provides valuable content. The data was only collected from one school, and the sample size was rather small, which are two of the study's weaknesses.

More studies on the impact of gender on oral health outcomes could optimize treatment strategies. Collaboration between engineers and dental professionals will likely drive further advancements in prosthetic design and functionality.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding.

CHITOSAN-STABILIZED LIPID VESICLES FOR SUSTAINED RELEASE AND PROLONGED ANALGESIC EFFECTS OF INDOMETHACIN IN A SOMATIC PAIN MODEL IN MICE (Abstract): The evolution of pharmaceutical nanotechnology enhances the flexibility of drug delivery by using carrier systems to target specific tissues, enabling controlled release at optimal concentrations. The inclusion of nonsteroidal anti-inflammatory drugs (NSAIDs) in nanocarriers presents a promising approach for achieving sustained release and improving the pharmacodynamic effects. We **aimed** to evaluate the in vivo kinetic release profile and the impact of indomethacin (IND) encapsulated in lipid vesicles on somatic nociceptive reactivity in mice. **Materials and methods:** Lipid vesicles were prepared using a molecular droplet self-assembly method, incorporating phosphatidylcholine and chitosan (CHIT) to encapsulate IND. The *in vivo* evaluation involved administering IND-loaded lipid vesicles to male Swiss mice and assessing their analgesic effects using the hot plate test, a standard method for measuring somatic pain. Blood samples were collected at different intervals to determine the release kinetics of IND, with concentrations measured by high-performance liquid chromatography. **Results** indicated that IND encapsulated in lipid vesicles exhibited a sustained release profile compared to the direct administration of the drug. The treatment with IND-loaded microvesicles resulted in significantly prolonged analgesic effects, as shown by extended latency times in the hot plate test. The release profile of IND from lipid vesicles, composed of phosphatidylcholine and stabilized with CHIT, demonstrated a gradual and controlled drug release, correlating with extended pain relief. **Conclusions:** These findings confirm the potential of lipid-based vesicles, as effective carriers for IND, offering sustained drug release and prolonged analgesic effects in a somatic pain model. **Keywords**: LIPID VESICLES, INDOMETHACIN, IN VIVO RELEASE, HOT PLATE, MICE.

INTRODUCTION

Nanotechnology applications in medicine, known as nanomedicine, involve the use of nanomaterials for diagnosing, monitoring, controlling, preventing, and treating diseases (1). Nanomaterials possess unique physicochemical properties distinct from their conventional counterparts due to their small size, making them valuable in drug development (2). These properties, such as altered pharmacokinetics, the ability to cross biological barriers, potential toxicity, and persistence in the environment and human body, must be carefully examined under use conditions (3, 4).

Lipid nanoparticles have emerged in the pharmaceutical industry as promising carriers for therapeutic agents. Liposomes, an early form of lipid nanoparticles, are versatile nanocarriers capable of transporting both hydrophobic and hydrophilic molecules, including small molecules, proteins, and nucleic acids. Many liposome-based drug formulations have been approved and successfully used in medical practice (5). Traditional drugs often face limitations in pharmacokinetics, low bioavailability, and high toxicity, which can restrict their use (6). Nanotechnology and nanomedicine have advanced in overcoming these issues, enhancing pharmacodynamic effects and improving disease detection, diagnosis, and treatment (5). With their small size, nanosystems reduce toxicity and improve pharmacokinetic parameters, such as distribution, prolonged circulation time, targeted release, higher intracellular concentration, and enhanced drug solubility and stability (6, 7).

A key area of research is enhancing the therapeutic profile of non-steroidal anti-inflammatory drugs (NSAIDs) with nanoparticles. NSAIDs are widely used to treat inflammatory diseases, but their long-term use can lead to side effects, especially gastrointestinal toxicity, due to repeated administration. Nanoparticle-based approaches offer an intriguing solution to improve NSAID safety and efficacy (8-10).

The 1-(4-chlorobenzoyl)-5-methoxy-2-methyl-1H-indole-3-acetic acid derivative indomethacin (IND) is a nonsteroidal anti-inflammatory drug (NSAID). Its structure is characterized by an indole acetic acid core with additional functional groups that contribute to its activity. The structure includes a chlorobenzoyl group attached to the indole ring, along with a methoxy group and a methyl group, which enhance the molecule's stability and potency as an anti-inflammatory agent. It is practically insoluble in water, which limits its absorption in aqueous environments (11). IND is rapidly absorbed from the gastrointestinal tract following oral administration, reaching peak plasma concentrations within 2 to 4 hours, though this can vary based on the formulation and presence of food. It has a bioavailability of approximately 90-95%, though high variability can occur among individuals. It is approximately 90% bound to plasma proteins, predominantly albumin, which limits its free fraction in circulation but also contributes to its longer half-life and tissue distribution. The drug undergoes extensive hepatic metabolism, primarily by demethylation and deacetylation, and is eventually excreted in urine and feces both as metabolites and in small amounts as the parent compound. Its elimination half-life typically ranges between 4 to 5 hours but can vary depending on patient-specific factors such as liver and kidney function (12).

IND exerts its effects primarily by inhibiting cyclooxygenase (COX) enzymes, specifically COX-1 and COX-2, thus reducing the inflammatory response, pain, and fever, making it effective in the treatment of conditions such as arthritis, gout,

and dysmenorrhea (13, 14). However, its inhibition of COX-1 also reduces the protective effects of prostaglandins in the gastrointestinal tract and kidneys, contributing to common adverse effects like gastrointestinal irritation, ulceration, and renal impairment. Its strong inhibition of COX enzymes also explains its potential cardiovascular risks, as prostaglandins involved in vasodilation and platelet inhibition are reduced, potentially leading to increased blood pressure and risk of thrombotic events (15). Incorporating IND into nanosystems may offer significant pharmacological benefits, including reduced gastrointestinal irritation and enhanced anti-inflammatory and analgesic effects.

The **purpose** of this study was to assess the impact of IND encapsulated in nanosystems on somatic nociceptive reactivity in rats.

MATERIALS AND METHODS

Substances. The materials used for nanoparticle preparation were procured from Sigma-Aldrich Chemical Co., Steinheim, Germany (www.sigma-aldrich.com). These included CHIT (catalog code: C3646; derived from crab shells, molecular weight: 310,000 g/mol 80% degree of N-deacetylation, polydispersity index of 3.26), IND (catalog code: I7378; 98.5% purity; molecular weight: 357.79 g/mol), phosphatidylcholine (catalog code: P5638; type II-S, soy-derived, containing 14–29% choline), cholesterol (catalog code: C8667; ≥99% purity; molecular weight: 386.65 g/mol), chloroform (catalog code: C2432; stabilized with 100–200 ppm amylene; ≥99.5% purity; molecular weight: 119.38 g/mol), glacial acetic acid (catalog code: 695092; ≥99.7% purity; molecular weight: 60.05 g/mol), and ethyl alcohol (catalog code: E7148; 95% purity; molecular weight: 46.07 g/mol).

Preparation of lipid vesicles entrapping IND. Lipid vesicles containing IND were prepared using a molecular droplet self-assembly method. Ethanol was used as the solvent for the lipids, cholesterol, and IND, while CHIT was dissolved in 0.5% glacial acetic acid.

In the preparation, 0.09 g of soy lipid was mixed with 0.66 mL of ethanol, and 0.015 g of cholesterol and 0.01 g of IND were each dissolved in 1 mL of ethanol. The combined lipid and IND solution (1.66 mL) were subjected to sonication at 25% amplitude for 10 minutes at 29°C using a Bandelin SONOPULS 2450 ultrasonic homogenizer, providing 20,000 kJ of energy (16). This sonication step transformed multilamellar structures into unilamellar vesicles, with their size controlled by ultrasound amplitude. The resulting mixture was then injected into 8.33 mL of double-distilled water (22-23°C), forming a slightly translucent suspension of IND-loaded lipid vesicles (IND-vl). Separately, 1.66 mL of the ethanol mixture was added to 8.33 mL of 0.25% CHIT solution under magnetic stirring (800 rpm for 20 minutes at 22°C), resulting in the formation of IND-loaded vesicles (IND-ves). Both dispersions were further stirred for an additional 5 minutes (16). The inclusion of CHIT altered the vesicle size and morphology, improving the colloidal stability. The pH of both dispersions was measured using a Sartorius Professional PP-50 pH meter. To remove excess lipids and unencapsulated drug, the dispersions were dialyzed for 2 hours using 12,000 Da MWCO tubular membranes (catalog code: D6191-25EA, Sigma-Aldrich). This process adjusted the pH to physiological levels, with the IND suspension reaching a pH of 7.0 and the CHIT-coated vesicles (IND-ves) achieving a pH of 6.7 (16).

Animals. The experiments were carried out on male white Swiss mice (20-25 g), acquired from the National Medical-Military Institute for Research and Development, Baneasa, Bucharest, Romania, the Biobase at "Grigore T. Popa" University of Medicine and Pharmacy of Iasi and CEMEX (Advanced Research and Development Center for Experimental Medicine) in Iasi, Romania. The mice were kept in individual plexiglass cages and given a 7-day acclimatization period in a controlled laboratory setting, where the temperature was maintained at 21±2°C, humidity ranged from 50% to 70%, and a 12-hour light/dark cycle was followed. Standard granulated food and tap water were available *ad libitum*, with daily food intake recorded and the animals' behavior closely monitored.

The protocol of the experiments. For the experiment, the animals were randomly assigned to groups of five and treated orally using an esophageal-gastric device with a single daily dose as follows: Group 1 (Control) received 0.1 mL of distilled water per 10 g of body weight; Group 2 (IND) was administered IND solution at 5 mg/kg body weight; and Group 3 (IND-ves) received CHIT-based vesicles containing IND at 5 mg/kg body weight.

The release profile of IND from the lipid vesicles was determined by conducting repeated measurements of the drug concentration in the blood. The mice were anesthetized with 1% isoflurane, and 0.3 mL of blood was collected prior to the administration of IND-ves. Subsequent blood samples were taken at intervals of 15 minutes, 30 minutes, 60 minutes, 90 minutes, 2 hours, 3 hours, 4 hours, 5 hours, 6 hours, and 8 hours post-administration. The concentration of IND released into the bloodstream was analyzed using high-performance liquid chromatography (HPLC) with an Agilent 1100 HPLC system (Santa Clara, CA, United States), employing ultraviolet (UV) absorbance detection at a wavelength of 254 nm.

The somatic pain model utilized in this research involved the hot plate test (Deuis, 2017). The baseline latency, measured before drug injection, was found to be 4.2 ± 0.2 seconds (mean ± standard deviation). A cut-off time of 10 seconds was implemented to prevent any potential tissue damage. The differences observed between experimental and baseline latencies were used as indicators of analgesia; specifically, longer latency times suggested analgesic effects, while shorter latencies indicated hyperalgesia (17,18). Latency times in response to the thermal stimulus applied to the paws were assessed at several points: before the experiment and at 15, 30, 60, 90, and 120 minutes, as well as at 4, 6, and 8 hours after administration of the substances. To quantify the intensity of the antinociceptive effect, the latencies were converted into a percentage of the maximum possible effect (%MPE), calculated using the formula: % MPE = (measured latency – baseline latency) x 100 / (cut-off time – baseline latency) (19). Changes in pain threshold following administration of the lipid vesicles with IND were considered significant when they exceeded 60% MPE; values below this threshold, while statistically notable, raised concerns regarding their biological significance. In this somatic pain model, an extension of reaction time compared to baseline measurements indicated an antinociceptive effect of the substances under study, whereas a decrease in latency suggested a hyperalgesic response to the compounds tested (18).

The protocol followed the guidelines established by the Ethics Commission of "Grigore T. Popa" University of Medicine and Pharmacy of Iasi (Ethical Approval Certificate No. 362/28.11.2023; Project

Authorization No. 69/15.01.2023), in accordance with current European ethical standards (20).

Statistical processing of data. Data were reported as mean values with standard error of the mean (± SEM). Statistical significance was evaluated using *SPSS Statistics for Windows version 13.0,* employing the ANOVA method. A P-value of less than 0.05 was interpreted as statistically significant when compared to the control group.

RESULTS

In our previous studies, we developed novel polymeric vesicles that encapsulate IND, with an average size of 317.6 nm and a polydispersity index of 0.364, demonstrating good suspension stability (Zeta potential of 24 mV). In vitro studies revealed a sustained release of IND from the lipid vesicles, unlike the non-encapsulated drug. Furthermore, the IND-loaded vesicles exhibited excellent in vitro hemocompatibility (16).

We continued the researches investigating the in vivo release profile of IND from carrier systems and evaluating the effects of the IND-loaded lipid vesicles administration on the nociceptive reactivity in mice.

The in vivo kinetic assessing of IND incorporated into IND-ves shows no detectable release of the drug during the initial 15 minutes. At 30 minutes, a small percentage begins to appear, marking the onset of release. By 2 hours, approximately 75% of the total release is achieved. The release reaches its peak at 3 hours, corresponding to 100% of the maximum release (fig. 1). Following this peak, the drug concentration decreases gradually due to metabolism and clearance from the bloodstream. By 6 hours, about 50% of the maximum release remains, dropping further to 16% at 8 hours. After 10 hours, the concentration declines close to baseline, indicating nearly complete clearance of the drug (fig. 1). This release profile highlights a controlled and sustained release of IND over time, demonstrating the efficiency of the nanoparticles in prolonging drug availability compared to free IND.

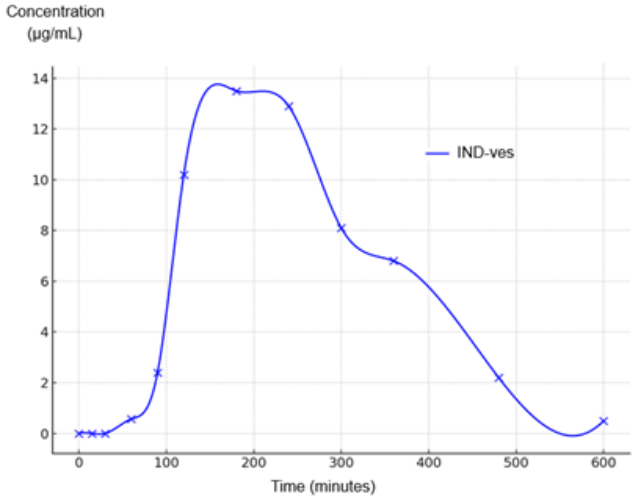

Fig. 1. The *in vivo* kinetic release profile of IND from IND-ves

The statistical analysis of the hot plate test demonstrates that free IND significantly increased the latency time of the animals' response following thermal noxious stimulation. A statistically significant increase was observed between 15 minutes and 90 minutes (**p > 0.01), as well as at 2 hours (*p > 0.05) post-administration (fig. 2). However, the effect did not persist beyond this period, as the response latency rapidly decreased and the antinociceptive effect was entirely lost by 180 minutes (fig. 2). These findings are consistent with previous studies showing the antinociceptive properties of IND in various pain models.

When IND was encapsulated in soft vesicles, it resulted in a notable prolongation of the animals' response latency to experimentally induced pain. The significant effects (**p > 0.01) were observed between 90 minutes and 6 hours, with the response latencies lasting longer compared to free IND. The antinociceptive effect of IND-ves peaked during this period, but the effects diminished after 8 hours.

Free IND significantly increased %MPE during the first 2 hours, with the peak effect observed at 60 minutes post-administration. During the initial hour of the experiment, the effect was notable, exceeding 50% MPE, indicating a submaximal antinociceptive response. However, the effect waned after 120 minutes, with %MPE dropping below 50% (fig. 3).

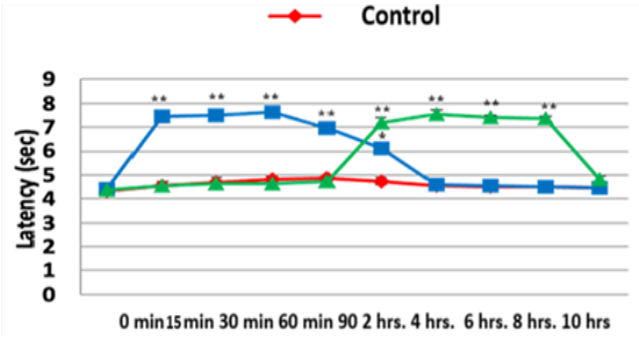

Fig. 2. The latency time response to thermal noxious paw stimulation in hot plate test in mice

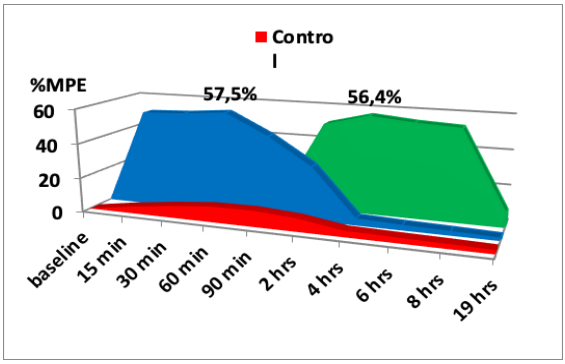

Fig. 3. Quantification of the analgesic activity of IND and IND-ves in hot plate test in mice

In contrast, IND encapsulated in soft vesicles demonstrated a delayed onset of %MPE, becoming evident around 2 hours post-administration. The %MPE exceeded 50% between 120 minutes and 8 hours during the experiment, before abruptly declining thereafter. These results indicate that vesicle-encapsulated IND offers a more prolonged antinociceptive effect compared to the free drug form.

DISCUSSION

The advancement of pharmaceutical nanotechnology expands drug application possibilities, as carrier systems enable the targeted delivery of active compounds to specific tissues, releasing them within an effective concentration range to increase the accumulation of anti-inflammatory agents. In recent years, nanosystems incorporating NSAIDs have shown the ability to enhance anti-inflammatory effects while reducing side effects (21). A diverse array of hybrid nanoparticles with anti-inflammatory agents has been synthesized, characterized, and studied. These nanoparticles act as carriers, loaded with anti-inflammatory drugs to create a controlled delivery system for active substances. Each nanoparticle structure has unique properties that optimize delivery to target tissues (22, 23).

The use of biocompatible and biodegradable polymers is a major advantage, as they allow the carrier to degrade naturally, minimizing toxicity (24, 25). Natural polymers like starch, collagen, alginate, cellulose, chitosan, and chitin are particularly appealing for developing systems to incorporate pharmacologically active agents. Among these, chitosan is a biocompatible, biodegradable, and non-toxic polymer with exceptional properties. It exhibits antibacterial effects, film-forming ability, high mechanical strength, and good thermal stability. Numerous chitosan-based bio nanocomposites with enhanced physical and chemical properties have been developed to create novel drug-loaded nanoformulations (26).

Research has presented numerous innovative approaches for creating IND-loaded systems, including phospholipid conjugates designed to improve IND's transport and controlled release. These methods focus on enhancing the solubility, stability, and release profile of IND within nanoformulations (27). Lipid-based nanocarriers, such as lipid emulsions, leverage phospholipids and surfactants have been developed to improve the solubility and bioavailability of IND (28, 29). Liposomal formulations, incorporating sterically stabilized vesicles with stearyl amines and cholesterol, enhance drug stability and provide sustained release (30).

Other biocompatible carrier systems for modified release of IND were developed by embedding IND within copolymeric networks of poly(2-hydroxyethyl methacrylate-co-3,9-divinyl-2,4,8,10-tetraoxaspiro [5.5]-undecane) and poly (aspartic acid) as a stabilizing colloid, or hyaluronic acid and four variants of poly(itaconic anhydride-co3,9-divinyl-2,4, 8,10-tetraoxaspiro[5.5] undecane) via poly-merization methods (31-33).

Some researchers developed original systems based on indomethacin-loaded microparticles composed of poly(lactic-co-glycolic acid), prepared using solvent evaporation and freeze-drying for enhanced stability (34). Keßler *et al*. prepared amorphous solid dispersions loading indomethacin by embedding the drug into polymer matrices such as poly(vinyl pyrrolidone) or poly(lactic-co-glycolic acid), employing

techniques like hot melt extrusion or solvent evaporation (35). Moreover cyclodextrin-based systems for loading IND were obtained using various techniques, such as solvent evaporation, co-precipitation, or spray-drying, for controlled and targeted drug delivery uses (36-38).

In our researches, the in vivo assessment revealed that IND, when encapsulated in lipid vesicles stabilized with CHIT, exhibited a significantly prolonged and controlled release compared to the direct administration of the drug. The IND-loaded micro-vesicles not only enhanced the duration of the analgesic effect but also extended the overall therapeutic response in the hot plate test, a common method for evaluating pain sensitivity in animals. In particular, the release profile of IND from lipid vesicles, composed of phosphatidylcholine and stabilized with CHIT, showed a sustained and gradual release of the drug over time, which correlated with a longer-lasting antinociceptive effect. This extended analgesic activity was in stark contrast to the rapid onset and quick decline of pain relief observed with the non-encapsulated drug. The onset of the antinociceptive effect of IND-vesicles after a two-hour latency period can be attributed to the release mechanism of IND from the lipid vesicles, which aligns with the in vivo drug release kinetics.

The results demonstrated a clear relationship between the in vivo release kinetics of IND from the lipid-based vesicles and the prolonged pain relief observed in the somatic pain model.

CONCLUSIONS

The administration of IND-loaded lipid vesicles demonstrated a sustained release profile in comparison to direct drug administration. Treatment with the micro-vesicles containing IND resulted in a longer-lasting analgesic effect in the hot plate test, unlike the non-encapsulated drug. A clear correlation was found between the in vivo release of IND from lipid vesicles made of phosphatidylcholine and CHIT, and the extended antinociceptive activity in mice. Overall, our results support the effectiveness of lipid vesicles as carriers for IND, facilitating controlled drug release and prolonged analgesic effects in this somatic pain model.

DESIGN AND OPTIMIZATION OF CHITOSAN-BASED NANOFIBROUS SCAFFOLD FOR THE DELIVERY OF NATURAL BIOACTIVE COMPOUNDS (Abstract): The **aim** of this study was to obtain and optimize chitosan (CH)/poly(vinyl alcohol) (PVA)-based nanofibrous scaffold with controlled nanoscale characteristics, by identifying the key electrospinning parameters. The optimized scaffold was subsequently loaded with natural bioactive compounds (ACs). **Materials and methods**: To achieve an optimal polymer composition, different concentrations of each polymer and various CH/PVA ratios (v/v) were investigated until a formulation capable of generating uniform nanofibers (NFs) under experimentally optimized electrospinning conditions was obtained. Based on this optimized matrix six formulations were prepared: CH/PVA@ARG, CH/PVA@ARG-ALA, CH/PVA@ARG-RJ, CH/PVA@ALA, CH/PVA@CUR, and CH/PVA@CUR-ALA, by incorporating L-arginine (ARG), allantoin (ALA), royal jelly (RJ), and curcumin (CUR), known for their antioxidant, antiseptic, and wound-healing properties. Fiber morphology was initially assessed by optical microscopy, followed by detailed analysis using scanning electron microscopy (SEM) to confirm the fibrous architecture and determine the fiber diameter. **Results**: The optimization process yielded uniform, bead-free CH/PVA NFs at a 1:3 ratio and a total polymer concentration of 6.25%. The optimized matrix enabled the incorporating ACs at selected concentrations (10% ARG, 4% ALA, 3% CUR, 3% RJ). For synergistic combinations, concentration adjustments were required to preserve fiber morphology and avoid rheological instabilities associated with cumulative AC loading. **Conclusions**: CH/PVA@ACs NFs with uniform, bead-free fiber morphology suitable for wound healing applications, were prepared. **Keywords**: CHITOSAN, ACTIVE COMPOUNDS, OPTIMIZATION, ELECTRO-SPINNING.

INTRODUCTION

One of the main innovations in the development of advanced wound dressings is the application of nanotechnology. In this context, nanofibers (NFs) (nonwoven materials) synthesized by electrospinning represent one of the most promising and advantageous approaches. These NFs can mimic the three-dimensional (3D) architecture of the extracellular matrix (ECM) and modulate cellular behavior, thereby promoting the cascade of processes involved in tissue regeneration (1). The term wound is a general concept, that describes several types of skin damage or injury. Wounds can be classified according to several criteria, such

as: healing time, etiology, mechanism of injury, complexity, depth, degree of contamination, risk of post-operative infection and wound bed characteristics (2).

An effective wound dressing must satisfy three key requirements: it should be able to absorb exudate, alleviate pain, and protect the wound from secondary infections. In addition, the wound dressings to promote tissue repair and regeneration should have key properties, including antimicrobial activity, antioxidant potential, appropriate mechanical strength and biodegradability (3). Because the traditional gauze dressings have many disadvantages, including traumatic removal and a tendency to dehydrate the wound bed, new advance biomaterials have been developed. The modern dressings are designed to come into direct contact with the wound surface and to actively support tissue regeneration without inducing additional tissue damage. In clinical practice, NFs represent innovative dressings capable of providing controlled release of various active compounds (ACs) with important biological effects on wound healing, such as antioxidant, antibacterial, and immunomodulatory properties. In addition, NFs can maintain a moist, oxygenated, and sterile microenvironment that is essential for accelerated and effective wound healing. Furthermore, the development of composite biomaterials combining natural and synthetic polymers has led to improved biocompatibility, reduced toxicity, and enhanced wound-healing efficacy (4).

Chitosan (CH) is a polysaccharide composed of beta-(1-4)-linked 2-amino-2-deoxy-D-glucose (D-glucosamine) and N-acetyl-2-amino-2-deoxy-D-glucose (N-acetyl-D-glucosamine) units. It is obtained through alkaline deacetylation of chitin, which is extracted from the exoskeletons of arthropods as well as from the cell walls of certain fungi (5). Owing to its favorable physicochemical and biological properties, including non-toxicity, biodegradability, biocompatibility, and intrinsic bioactivity, CH is an important natural polymer for biomedical applications (5). CH exhibits significant hemostatic effects due to interactions between its protonated amino groups (NH_3^+) and the negatively charged membranes of erythrocytes. In addition, CH exhibits analgesic properties by reducing bradykinin levels at the wound site, as well as anti-inflammatory effects, which is attributed to interactions between NH_3^+ groups and wound components, leading to attenuation of the inflammatory response (6). Furthermore, CH possesses antibacterial properties by forming a polymeric film around bacterial cells that inhibits cellular exchanges and nutrient transport (7-11).

Poli(vinyl alcohol) (PVA) is obtained through the free-radical polymerization of vinyl acetate, resulting in polyvinyl acetate (PVAc), followed by partial or complete hydrolysis of the acetate groups along the polymer backbone. During this process, acetate groups are replaced by hydroxyl (-OH) groups, and the degree of hydrolysis strongly influences the solubility, crystalline and physicochemical properties of the resulting PVA (12, 13). Due to its biocompatibility and low toxicity (14), PVA is frequently blended with natural polymers such as CH during electrospinning to produce NFs for tissue engineering applications (15).

L-Arginine (ARG) is an essential α-amino acid component of the urea cycle, a precursor to many biochemical pathways involved in cell physiology. ARG plays a key role in wound healing through two main mechanisms: (i) transformation of

ARG under the influence of arginase, with the obtaining of ornithine, precursor of L-proline, an important amino acid in the process of collagen synthesis; (ii) oxidative deamination of ARG, until obtaining nitric oxide (NO), a bioactive molecule involved in the processes of reepithelialization, cell proliferation, collagen synthesis and angiogenesis (16).

Allantoin (ALA), chemically known as 5-ureidohydantoin, is a natural compound that is widely regarded as safe for topical administration and exhibits low toxicity (17). ALA can be synthesized from urea and is also found biologically as an intermediate in the metabolism of certain plants and microorganisms, as well as a final product of purine catabolism in mammals. In mammals, it is formed via non-enzymatic degradation of uric acid in the absence of uricase, under the influence of reactive oxygen species (ROS) (18,19). ALA exhibits multiple biological effects, including antioxidant properties (20), anti-inflammatory activity, manifested by the reduction of pro-inflammatory cytokines, such as interleukin-1 (IL-1), interleukin-6 (IL-6), and tumor necrosis factor-alpha (TNF-α) (21), as well as keratolytic, moisturizing, and immunomodulatory properties (22).

Curcumin (CUR), is a polyphenolic complex derived from turmeric (*Curcuma longa L.*) that exhibits a broad spectrum of biological activities (3). Curcumin I is the main component, accounting for 60-70% of the total curcuminoid content, followed by demethoxycurcumin (curcumin II, 20-27%), and bisdemethoxycurcumin (curcumin III, 10-15%) (23). The scientific data indicate that curcumin I is largely responsible for the biological activity of the curcuminoid complex (3). It is widely recognized for its antioxidant, antimicrobial, anti-inflammatory and antidiabetic properties (24, 25).

Royal jelly (RJ) is a highly valued natural product produced by honeybees (*Apis mellifera*), whose composition varies depending on bee species, botanical origin, and seasonal factors. It is primarily composed of water (50-60%), proteins (9-18%), carbohydrates (11-23%) and lipids (3-6%), and also contains vitamins (B complex, C, A, E), essential amino acids, minerals (Ca, Mg, Na, Cu, K, Mn, Fe, Zn), enzymes, hormones, polyphenols, nucleotides, and heterocyclic compounds (26-29). The beneficial effects of RJ in the treatment of skin disorders are largely attributed to its ability to reduce transepidermal water loss and to restore the lipid barrier (30), thereby maintaining an optimal degree of hydration at the wound site, which is essential for the healing process. In addition, RJ exhibits antifungal activity mainly due to royalisin (26), antimicrobial activity mediated by royalisin, jelleins (1-3), and the major RJ protein 4 (MRJP4) (22, 27-31), antibacterial effects associated with 10-hydroxy-2-decenoic acid (10-HDA), major RJ protein 2 (MRJP2), and MRJP4 (21, 22, 26), as well as antioxidant activity primarily attributed to its phenolic compounds and MRJP2 (22, 27).

The objective of this study was to design and optimize a CH/PVA-based nanofibrous matrix for the efficient encapsulation and delivery of the natural ACs such as CUR, ALA, ARG, and RJ.

MATERIALS AND METHODS

Reagents. Chitosan (CH) (medium molecular weight, 75-85% deacetylation grade), polyvinyl alcohol (PVA), 87-89% hydrolyzed, high molecular weight, aver-

age M.W. 88.000-97.000 were purchased from Alfa Aesar; L-arginine (ARG), Allantoin (≥98% purity) (ALA), curcumin (CUR) analytical standard (M.W: 368.38) were purchase from Supelco; pure Royal jelly (RJ) was purchased from Melidava with 1.59 % (wt/wt) 10-Hydroxy-2-decenoic acid; glacial acetic acid (≥ 99.7%) were purchased from Sigma Aldrich, distilled water (DW), tween 80.

Optimization of CH/PVA ratio for nanofibrous scaffold preparation

The optimization of CH and PVA blend ratio was systematically investigated to obtain nanofibrous scaffold with optimal characteristics, including reduced fiber diameter and bead-free structure. CH solutions (1%, 2%) were prepared by dissolving defined amounts of high molecular weight CH in glacial acetic acid, while PVA solutions (3%, 6%, 7%, 8%, 10%) were prepared by dissolving corresponding PVA amounts in deionized water under heating to ensure complete polymer dissolution. The two polymer solutions were subsequently combined in different volume ratios (CH: PVA - 1:1, 1:2, 1:3, 1:8, 2:6, 3:7) under continuous stirring for approximately 20 min, followed by equilibration at room temperature for 30 min to allow for air bubble removal. The resulting mixtures were stirred at room temperature until homogeneous solutions suitable for electrospinning were obtained.

Optimization of CH/PVA/ACs ratio for CH/PVA@ACs NFs preparation

After identifying the optimal CH:PVA ratio, ACs, namely CUR (1%, 2%, 3%, 4%), ALA 1%, 2%, 3%, 4%, 5%), ARG (1%, 3%, 5%, 10%, 15%), and RJ (1%, 2%, 3%, 4%), were incorporated at various concentrations. The resulting mixtures were stirred at room temperature until homogeneous solutions suitable for electrospinning were obtained.

Electrospinning process

The CH/PVA nanofibrous scaffold and CS/PVA@ACs NFs were prepared by electrospinning using a Nanospinner device (Inovenso) equipped with a high-voltage power supply, syringe pump, spinneret, and a grounded collector. The polymers solutions were loaded into a syringe serving as positive electrode, while the collector acted as the counter electrode. Electrospinning parameters, including the applied voltage, flow rate, and needle tip-to-collector distance were systematically optimized in conjunction with the polymer ratio to obtain uniform, bead-free NFs. The collected fibers were deposited on to aluminum foil and dried under room temperature prior to further characterization.

Characterization of the CH/PVA nanofibrous scaffold and CH/PVA@ACs NFs

CH/PVA nanofibrous scaffold and CH/PVA@ACs NFs, including single formulations (CH/PVA@ARG, CH/PVA@ALA, CH/PVA@CUR) as well as combined synergistic systems (CH/PVA@ARG-ALA, CH/PVA@ARG-RJ, CH/PVA@CUR-ALA), were first examined by macroscopic and low-magnification microscopic observation (40X) to verify the presence of continuous fibrous structures. Subsequently, fiber morphology and diameter were analyzed by scanning electron microscopy (SEM, Inspect S, 30 keV) (32). Prior to imaging, the samples were sputter-coated with a thin gold layer to minimize charge accumulation. Fiber diameter distributions were determined using *Phenom Fiber Metric* software, and the results are expressed as mean ± standard deviation (SD) based on three independent measurements (n = 3).

RESULTS

In order to optimize the formulation for the fabrication of CH/PVA nanofibrous scaffold with uniform morphology, bead-free structure, high yield and reduced diameter, a series of processing and formulation parameters were systematically investigated through multiple experimental trials. Specifically, the effect of CH concentration (1%, 2% wt/v), PVA concentration (3%, 6%, 7%, 8%, 10%), CH: PVA polymer ratio (1:1, 1:2, 1:3, 2:6, 3:7, 1:8), applied voltage (13-17 kV), flow rate (0.1-0.3 mL/h), tip-to-collector distance (17-24 cm) and relative humidity (22-64%) were evaluated.

Based on the obtained results (tab. I), the CH/PVA (1:3 v/v) formulation with a total polymer concentration of 6.25%, electrospun at an applied voltage of 17 kV, a flow rate of 0.25 mL/h, and a tip-to-collector distance of 20-24 cm, was identified as the optimal composition. This optimized formulation consistently yielded uniform, bead-free NFs, as confirmed by SEM analysis (fig. 1). The micrographs reveal the successful formation of an interconnected nanofibrous network with smooth fiber surfaces and homogeneous morphology, thereby validating the optimization strategy and establishing this composition as the base matrix for subsequent functionalization using natural ACs.

*The parameters considered optimal used for obtaining the CH/PVA nanofibrous scaffold;

** One drop of tween 80 was added

For the electrospinning of the CH/PVA@ACs polymeric solutions, the same ranges of process parameters used for CH/PVA polymeric solution were applied. In this case, the only variable was the concentration of ACs incorporated into the polymer matrix (tab. II). The resulting CH/PVA@ACs nanofibers (NFs) were subsequently characterized by macroscopic and microscopic analyses (fig. 2).

*The ACs concentration (wt/v) considered optimal for obtaining the CH/PVA@ACs fibers

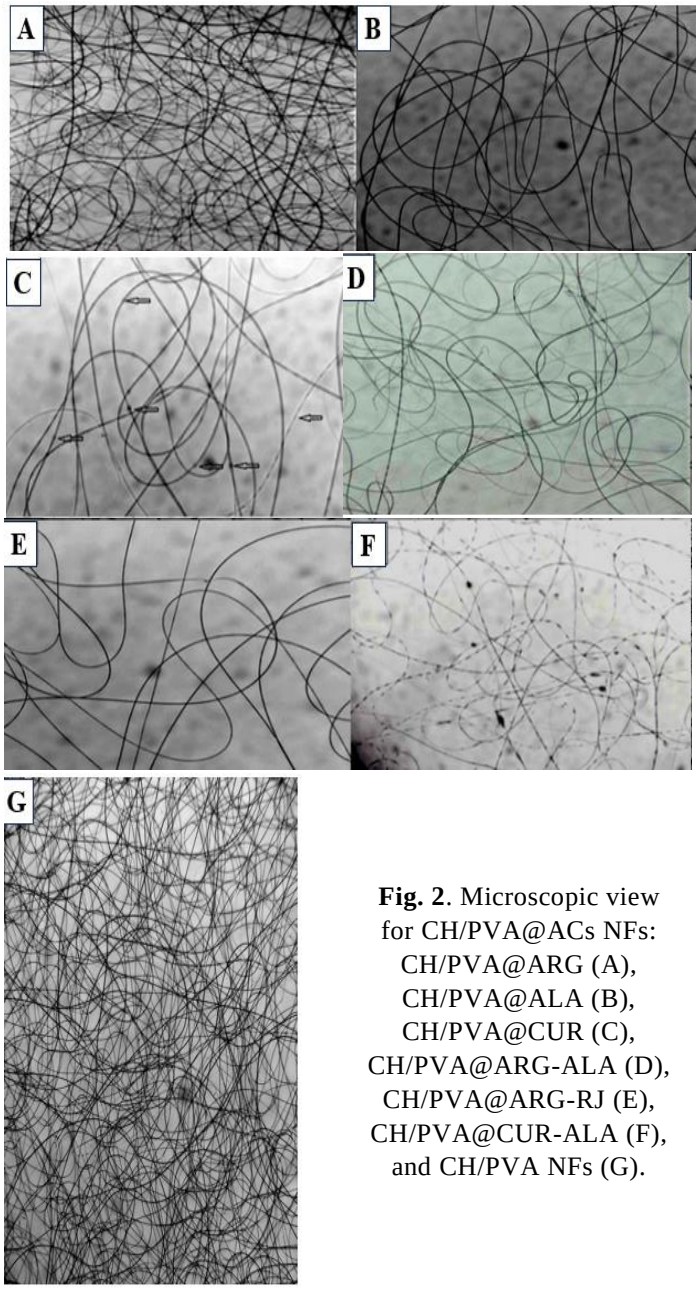

Fig. 2. Microscopic view for CH/PVA@ACs NFs: CH/PVA@ARG (A), CH/PVA@ALA (B), CH/PVA@CUR (C), CH/PVA@ARG-ALA (D), CH/PVA@ARG-RJ (E), CH/PVA@CUR-ALA (F), and CH/PVA NFs (G).

DISCUSSION

Analysis of the experimental data indicates that a minimum total polymer concentration of approximately 5% is required to obtain uniform, small-diameter NFs, above which the nanofibrous production yield increases markedly. Below this threshold, bead-like structures and polymer

fragments were predominantly observed, a behavior attributable to the low viscosity which is insufficient to stabilize the electro spun jet.

A progressive increase in the CH:PVA ratio in favor of PVA significantly improved fibers morphology. This effect can be explained by the formation of hydrogen bonds between PVA and the $-NH_2$, and -OH groups of CH, which reduces surface tension and weakens the strong intramolecular interactions within CH chains. This trend is reflected by the morphological transition from polymer fragments (CH 1% /PVA 3%, 1:1) to continuous fibers (CH 1% /PVA 8%, 1:3). Moreover, the addition of a surfactant (tween 80) further facilitated nanofiber formation by lowering surface tension. The electrospinning process parameters exhibited a complex interdependence. For low-viscosity polymer solutions, increasing the applied voltage led to pronounced jet instability in the electric field. In addition, the optimal flow rate was found to be inversely related to the total polymer concentration, with values of 0.1 mL/h for 7.6%, total polymer and 0.2 mL/h for 7.4% total polymer.

All ACs were successfully incorporated into the polymer matrix at the desired concentrations, requiring only minor adjustments of the operating parameters, which highlights the versatility and robustness of the optimized CH/PVA base formulation. For synergistic combinations, AC concentrations were selected based on individually optimized values, while considering the maximum loading capacity of the CH/PVA matrix and the need to preserve stable electrospinning conditions. Simultaneous loading of ACs at their individual maximum concentration led to cumulative rheological disruptions, resulting in process instability.

The ARG concentration was therefore fixed at 10%, since preliminary experiments showed that increasing it to 15% caused excessive solution conductivity, which destabilized the electrospinning jet and promoted droplet formation instead of continuous fibers. In addition, bead formation and surface defects were observed, while enhanced electrostatic interactions between positively charged ARG and protonated CH induced visible solution inhomogeneities, necessitating extensive re-optimization of the process parameters. The combination of 10% ARG with 3% RJ was successfully achieved, with RJ being homogeneously incorporated into the polymer matrix without altering the optimized electrospinning parameters. Increasing the RJ concentration above 3% led to significant changes in the rheological properties, mainly due to a marked increase in viscosity associated with the molecular complexity and variability of RJ, which destabilized the jet and resulted in non-uniform fibers.

For ALA, the concentration was limited to 4%, as higher amounts revealed its limited solubility in the CH/PVA system, leading to presence of undissolved particles that blocked the electrospinning needle. Moreover, the associated viscosity changes disrupted the electrospinning parameters, resulting non-uniform fibers with morphological defects. Although increasing the temperature could potentially improve ALA solubility, this approach would have induced additional instability into the system. Consequently, the combination of 3% ARG with 3% ALA was selected in order to preserve the optimized electrospinning parameters.

The CUR concentration was limited to 3% due to its hydrophobic nature, which

led to suspension formation at higher loadings, even in the presence of DMSO. Furthermore, the crystalline character of CUR interfered with jet stability and resulted in non-uniform fibers morphologies. Attempts to maintain the same ALA concentration used in the individual formulation within the synergistic CUR-containing systems were unsuccessful, as no stable electrospinning system could be achieved and defective fibers were obtained

CONCLUSIONS

The optimization of CH/PVA nanofibrous scaffold and the establishment of optimal ACs concentrations, both in individual and synergistic combinations, through balancing of solution rheological properties and electrospinning process stability, enabled the fabrication of nanofibers with the desired characteristics. This approach successfully addressed challenges related to limited solubility, viscosity variations, and cumulative rheological disruptions, while preserving the bioactivity of the incorporated natural compounds and ensuring reproducible fiber morphology.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest. The research was supported by a grant of the Ministry of Education and Research CCCDI-UEFISCDI, project no. PN-IV-PCB-RO-MD-2024-0246, within PNCDI IV.

ASSESSMENT OF ROOT CANAL OBTURATION AND THE ADHESION OF ENDODONTIC SEALERS TO THE DENTIN WALLS OF THE ROOT (Abstract)**:** This study aims to compare the quality of root canal obturation achieved using different obturation techniques and to evaluate the adaptation of the interface between epoxy resin- based sealants and gutta-percha to the dentin walls of the root canal. **Materials and methods:** Thirty-six extracted single-rooted human teeth were used, prepared according to a standardized protocol and filled with gutta-percha using different techniques (lateral condensation and vertical hot condensation), to evaluate, through radiological analysis (retro-dento-alveolar radiography) and optical microscopy, the following aspects: the quality and homogeneity of the root fillings, the adhesion of the sealer to the dentin root walls, and the apical and coronal seal of the endodontic filling. The data were statistically analyzed to identify differences between techniques ($p < 0.05$), using the F-test and ANOVA. **Results:** Radiographic analysis revealed significant differences in the homogeneity of the filling and the presence of voids between techniques, with vertical hot condensation yielding the best results, particularly in the apical third. Optical microscopy confirmed better adaptation of the sealants in the case of thermoplasticized gutta-percha techniques, while lateral condensation showed a higher incidence of marginal voids at the apical level. **Conclusions:** The obturation technique significantly influences the quality of root canal obturation. Vertical hot condensation ensures homogeneity and optimal adaptation. Combined radiographic and optical microscopy evaluation provides a comprehensive method for assessing obturation results. **Keywords:** ROOT CANAL FILLING**,** THERMOPLASTICIZED GUTTA-PERCHA, ROOT DENTIN**,** OPTICAL MICROSCOPY.

INTRODUCTION

Filling materials and techniques that facilitate the effective penetration of the sealer and gutta-percha (GP) into the complex endodontic canal system are considered effective methods for preventing microleakage and subsequent treatment failure (1). Proper root canal obturation can ensure complete sealing to prevent communication between the endodontic space and the periapical tissue (2). The quality of root canal obturations (length, homogeneity, taper) has been shown to be a risk factor for apical periodontitis following evaluations of root-canal-treated teeth, whether treated for pulpitis or prosthetic pulpectomies, or for pulp necrosis (3). The presence of carious lesions adjacent to coronal resto-

rations has been shown to be a risk factor for apical periodontitis in root-filled teeth that had previously undergone bio pulpectomy, with this condition being linked to both the patient's caries risk and poor coronal marginal seal (4).

The purpose of this study is to conduct an experimental *in vitro* comparative study to evaluate the efficacy of two root canal filling techniques - the cold lateral condensation technique and the thermoplastic gutta-percha injection technique - in order to highlight, through radiological analysis (retro-dento-alveolar radiography) and optical microscopy, the following aspects: the quality and homogeneity of root canal fillings, the adhesion of the filling material to the dentin walls of the root canal, and the apical and coronal seal of the endodontic filling

MATERIALS AND METHODS

Sample preparation. The study was conducted in accordance with the Declaration of Helsinki and was approved by the Ethics Committee of the Grigore T. Popa University of Medicine and Pharmacy in Iași (334/16/07/2023). To calculate sample sizes, we used the G*Power program (Heinrich-Heine University, Düsseldorf, Germany). We used an effect size of 0.5, considered a large effect according to Cohen's classification, a significance level of 0.05, and a power of 0.8. The results obtained indicate the need for a minimum total of 42 samples. Therefore, to obtain statistically relevant results, we will use a minimum of 14 samples for each study Lot.

Forty-two single-rooted teeth, free of carious lesions, extracted for orthodontic or periodontal purposes, were selected upon the recommendation of specialist physicians. The inclusion criteria used were as follows: single-rooted teeth, free of carious lesions, extracted for orthodontic or periodontal purposes, upon the recommendation of specialists, from patients aged between 18 and 40 years. Exclusion criteria: devitalized teeth, teeth with calcifications, internal or external resorption, incompletely formed apices, as observed clinically and radiologically.

The impacted teeth were divided into three lots (n=14) as follows:

Lot I: Teeth treated with endodontic filling using the cold lateral condensation technique with standardized gutta-percha points having a 2% taper (Gutta Percha Points, 0.02, Meta Biomed Europe GmbH, Mulheim an der Ruhr, Germany) and an epoxy resin-based endodontic sealer (Adseal Plus, Meta Biomed Europe GmbH, Mulheim an der Ruhr, Germany).

Lot II: Teeth endodontically treated using the hot vertical condensation technique with standardized gutta-percha points having a 4% taper (Gutta Percha Points, 0.04, Meta Biomed Europe GmbH, Mulheim an der Ruhr, Germany), the endodontic sealer (Adseal Plus, Meta Biomed Europe GmbH, Mulheim an der Ruhr, Germany), the heated plugger (Op-FILL, China), in combination with thermoplasticized gutta-percha using a device (Fast-Fill, Eighteeth, Nuremberg, Germany) to inject the gutta-percha in its plastic form.

Lot III (Control Lot): Anterior teeth with root canal fillings performed using various condensation techniques (monocon technique).

For each study Lot, new sets of rotary files (Orodeka Plex – V) were used, adapted to the motor (Endo-Radar, Wodpacker) using the crown-down technique. The teeth were shaped for root canal treatment using 5.25% NaOCl – 5 mL (CHLORAXID 5.25% – 400 mL) and a

sonic endoactivator (EA) (Endoactivator, Maillerfer, Dentsply Sirona, Germany), with a 15/0.2-sized tip (Refill Type, Maillerfer, Dentsply Sirona, Germany) for 60 seconds. Final irrigation with 20% EDTA solution – 5 mL (20% liquid EDTA – 20 mL) – 1 min. The irrigation protocol was the same for all study Lots. Subsequently, they were endodontically obturated using the cold lateral condensation technique and the hot vertical condensation technique in combination with thermoplasticized gutta-percha (Fast-Fill, Eighteeth, Nuremberg, Germany) in combination with an epoxy resin-based endodontic sealer (Adseal Plus, Meta Biomed Europe GmbH, Mülheim an der Ruhr, Germany). The final stage of specimen preparation was to perform the coronal filling using a resin-modified glass ionomer cement-based material (Ionofeel-F, Flow, Schulzer, Hanau, Germany) and a light-cured composite (Charisma, Kulzer GmbH, Hanau, Germany) in shade A3, as the final coronal restoration.

Radiological evaluation. Postoperatively, 2D radiographs were taken (using a Carestream CS 2200 machine, Kodak, Carestream Health, Inc., NY, USA) with the following parameters: 0.071 mGy, 7 mA, 70 kV, from two angles (vestibulo-oral and mesio-distal) to determine whether the root filling was tight and homogeneous, both apically and coronally.

TABLE I.

Parameters and scores for evaluating the quality of root fillings

Parameters	Criteria	Description	Score
Density	Appropriate	Absence of fill material in the root filling or between the root filling and the walls of the root canal	**0**
	Weak	Presence of fill material in the root filling or between the root filling and the walls of the root canal	**1**
Length	Appropriate	The root filling extends to within ≤ 2 mm of the radiographic apex	**0**
	Weak	The root filling extends beyond the radiographic apex or is more than 2 mm from the radiographic apex	**1**
Conicity	Appropriate	Conical and continuous root canal preparation, from the canal entrance to the apex, with the cross-sectional diameter becoming narrower at each point toward the apex.	**0**
	Weak	Inconsistent conicity from the canal entrance to the apical part of the filling or root filling deviated from the original canal	**1**

The analysis of endodontic fillings was performed according to the criteria for evaluating the quality of root canal fillings (Nur *et al*., 2014; El Ouarti *et al*., 2021), assigning scores of 0 or 1 based on the identified criteria (tab. I). Regarding coronal seal, scores of 0 (sealed coronal filling, absence of gaps between the filling and the coronal walls) and scores of 1 (coronal filling with gaps between the filling and the coronal walls) were assigned.

Microscopic analysis. These teeth were sectioned transversely at the amelocemental junction and longitudinally under water jet cooling using a 0.17 × 22 mm diamond disc (Flexible Double Side, BesQual Diamond Disc, Meta Dental), mounted on a straight handpiece, at

20,000 revolutions per minute. This diamond disc was used for both sectioning and finishing the specimen, which was then analyzed using a Zeiss Imager microscope (a1M Carl-Zeiss, Jena, Germany) equipped with an Axiocam digital camera. The images were obtained using AxionVisionRelease 4.7.1 software. A magnification of 50× was used in dark field (DF) mode. Measurement of the marginal gaps was performed using the 500/1000 µm scale provided by the Axion Vision Release software.

Statistical analysis. To analyze the parameters, the F-test was used—calculating the difference in mean and intra Lot standard deviation; this technique is an extension of the Student's t-test applied to the means of two or more Lots. After applying the ANOVA test, a Bonferroni correction (post-hoc Bonferroni) was performed. This correction reduces the error rate when testing multiple hypotheses.

RESULTS

Qualitative results-radiological images. Table II presents radiographic images of the analyzed samples from various angles and an evaluation of root canal obturation based on specific criteria.

TABLE II.

Radiographic images of the specimens obtained at different angles and evaluation of root canal obturation based on specific criteria.

Study Lots	Vestibulo-oral incidence	Evaluation criteria and scores	Meso-distal incidence	Evaluation criteria and scores
LOT I Tooth 4.4		Density **score 0** Length **score 0** Conicity **score 0** Coronal sealing **score 0**		Density **score 1** Length **score 0** Conicity **score 0** Coronal sealing **score 0**
LOT II		Density **score 0** Length **score 0** Conicity **score 0** Coronal sealing **score 0**		Density **score 0** Lenght **score 0** Conicity **score 0** Coronal sealing **score 0**
LOT III		Density **score 0** Lenght **score 1** Conicity **score 1** Coronal sealing **score 0**		Density **score 1** Lenght **score 1** Conicity **score 1** Coronal sealing **score 0**

Regarding Lot I, where the cold lateral condensation technique was applied to tooth 4.4, a compact, homogeneous, and tight root filling can be observed from the vestibulo-oral view, with a score of 0 obtained for all evaluated criteria. However, the mesio-distal view reveals the presence of air voids in the root filling, between the root filling and the root canal walls (density scored as 1), while the other criteria (length, taper, and coronal seal) scored 0. Thus, in the case of Lot II, tooth 2.2, where root canal obturation was performed using the vertical technique and thermoplasticized gutta-percha injection, the vestibulo-oral view reveals a tight, homogeneous filling throughout the working length, with evaluation criteria such as density, length, and taper receiving scores of 0. Regarding coronal sealing, the coronal filling is tight against the coronal walls without air gaps, resulting in a score of 0. From the mesio-distal view, a root and crown filling are thus observed that is tight and adequately compact, with scores of 0 for all evaluated criteria. In contrast, following the analysis from the vestibulo-oral and mesio-distal views of tooth 2.1, Lot III (already obturated using a monocom condensation technique), a non-homogeneous root obturation is observed, with the presence of air pockets along the entire length of the root canal (score 1), inconsistent taper from the canal entrance to the apical portion of the filling (score 1), the root canal filling ends approximately 2 mm from the radiographic apex (score 1), although the coronal seal has a score of 0.

Optical microscopy results. Analysis of the images obtained via optical microscopy (tab. III) highlights the level of adaptation between the coronal and root canal fillings, with a tight seal of the root canal filling at the coronal level achieved for all three Lots. Additionally, representative images for each Lot studied can be observed in the three areas of the root canals. Thus, for the sample from Lot I, there is adequate marginal adaptation of the endocanal filling at the level of each analyzed root third; however, large amounts of sealer are observed between the gutta-percha cones, indicating insufficient condensation of the cones, although a tight apical seal is achieved in the apical third. At the same time, in the sample from Lot II, good adaptation to the dentin walls is observed in the three analyzed zones, with a compact mass of gutta-percha and less sealer noted on the root walls and within the gutta-percha mass. For the samples in Lot III, a loss of integrity of the root canal filling is observed, especially in the middle third, with insufficient adaptation at the dentin walls, and air voids present in the gutta-percha mass. In the apical third, an enlargement of the apical orifice can be observed, with the apical closure being achieved more with sealer than with solid gutta-percha, posing an increased risk of microleakage.

To assess the marginal adaptation of the filling material to the root walls, we used the 500 µm or 1000 µm scale provided by the AxionVisionRelease 4.7.1 software.

Statistical results. The statistical results obtained indicate a statistical analysis between Lots based on the root third; thus, the paired comparison test values for the crown third (tab. IV) indicate significant differences between Lot II and Lot I ($p = 0.033$) and between Lot II and Lot III ($p = 0.017$), suggesting notable variations

among these Lots. The comparison between Lot I and Lot III is not statistically significant (p = 1.000), indicating similarity between these two Lots. Adjusting the p-values using the Bonferroni correction confirms the robustness of these conclusions.

For the median third (tab. V), significant differences are observed only between Lot II and Lot III (p = 0.007). The other comparisons (Lot II *vs.* Lot I and Lot I *vs.* Lot III) do not reach the adjusted significance threshold (p > 0.05). These results suggest that only Lot II shows a distinct variation from Lot III, while Lots I and III are relatively homogeneous.

TABLE III.

Representative images of a sample from each study Lot, obtained by optical microcopy

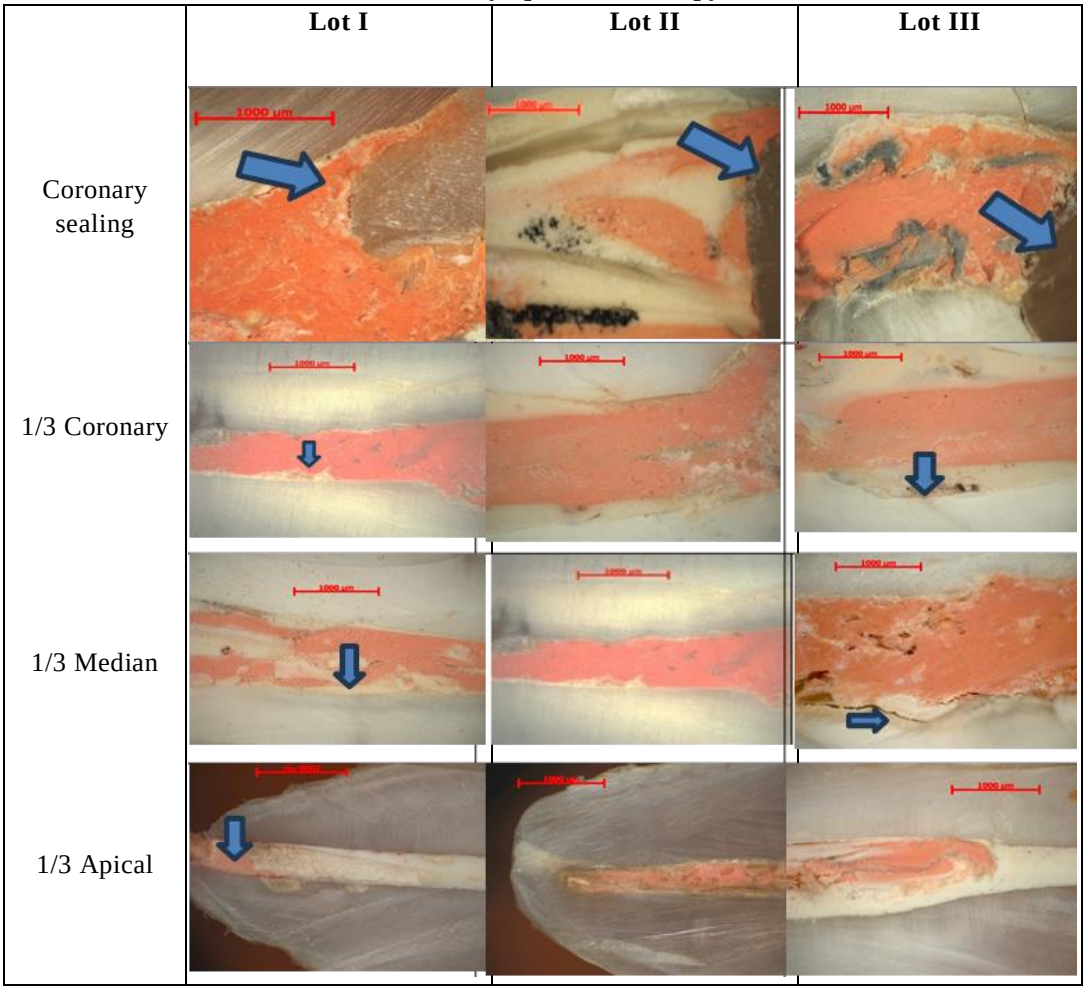

TABLE IV.

Paired comparison of Lots for the third coronary using the Mann-Whitney test with Bonferroni correction

Pairwise Comparisons of Lot					
Sample 1-Sample 2	Test Statistic	Std. Error	Std. Test Statistic	Sig.	Adj. Sig.[a]
Lot II- Lot I	7.200	2.828	2.546	.011	.033
Lot II- Lot III	-7.800	2.828	-2.758	.006	.017
Lot I- Lot III	-.600	2.828	-.212	.832	1.000

TABLE V.

Paired comparison of Lots for the median third using the Mann-Whitney test with Bonferroni correction

Pairwise Comparisons of Lot					
Sample 1-Sample 2	Test Statistic	Std. Error	Std. Test Statistic	Sig.	Adj. Sig.[a]
Lot II- Lot I	5.200	2.828	1.838	.066	.198
Lot II- Lot III	-8.600	2.828	-3.041	.002	.007
Lot I- Lot III	-3.400	2.828	-1.202	.229	.688

The analysis of the apical third (tab. VI) reveals a significant difference between Lot II and Lot III ($p = 0.002$), suggesting a clear distinction between these two Lots. Although the comparison between Lot II and Lot I approach significance ($p = 0.169$), it does not reach the 0.05 threshold. Similarly, the difference between Lot I and Lot III is not statistically significant ($p = 0.413$). These results indicate a more pronounced variation in Lot II, which differs from Lot III.

TABLE VI.

Paired comparison of Lots for the apical third using the Mann-Whitney test with Bonferroni correction

Pairwise Comparisons of Lot					
Sample 1-Sample 2	Test Statistic	Std. Error	Std. Test Statistic	Sig.	Adj. Sig.[a]
Lot II- Lot I	5.400	2.828	1.909	.056	.169
Lot II- Lot III	-9.600	2.828	-3.394	<.001	.002
Lot I- Lot III	-4.200	2.828	-1.485	.138	.413

Regarding the analysis of the degree of adaptation between the root-canal filling and the crown, the mean results obtained from the evaluation of radiographic scores and from the measurement of voids using a micrometer scale on optical microscopy images, as well as their standard deviations, are presented in table VII.

TABLE VII.

Mean values and standard deviations of radiological scores, and mean values of the voids measured using a micrometer scale on optical microscopy mages

	Lot I	Lot II	Lot III	p-value
Median (radiological scores)	0.70±0.47	0.55±0.21	0.80±0.41	0.232
Median (μm)	86±12	61±19	105±	0.175

The values presented in table VII show that, for both measurement methods, the lowest mean values were recorded in Lot II, followed in ascending order by the values obtained in Lot I and, finally, Lot III. Although the values varied across the Lots, statistical analysis using the parametric ANOVA One-Way test revealed the absence of any statistically significant differences between them.

DISCUSSION

The quality of root canal obturation certainly depends on the technique used. The results of our study showed that the vertical warm condensation technique with thermoplasticized gutta-percha ensures better adaptation of the material to the canal walls, especially in the apical third, compared to cold lateral condensation, which exhibited larger marginal voids and a more uneven distribution of gutta-percha. These observations are consistent with the literature, which reports difficulties in achieving a uniform filling in the apical area when using lateral or cold condensation techniques (5-8).

Microscopic and radiographic evaluations have shown that the three-dimensional adaptation of thermoplasticized gutta-percha reduces the risk of microleakage and improves the seal of the filling. Although epoxy resin-based endodontic sealants contribute to achieving root canal seal, some studies have shown that the use of the warm condensation technique improves the homogeneity of the root canal filling, with similar results observed in this study as well, particularly in the apical third. These observations suggest that optimal sealing of root canals depends not only on the materials used but also on the technique of compacting and adapting the gutta-percha, a finding confirmed by data from the specialized literature (9, 10).

Clinically, choosing an effective root-filling technique is essential for preventing the entry of microorganisms into the endodontic system and, consequently, for reducing the risk of reinfection and the occurrence of long-term failures (11). The control lot, which included samples obturated using various techniques, showed the greatest variability in results, supporting the importance of standardizing the procedure for predictable success. The statistical results indicate significant variability among the Lots studied, with Lot III exhibiting the largest marginal gaps and Lot II the smallest, confirming the superiority of the hot-compaction technique in terms of root canal obturation sealing. This trend of

increasing marginal gaps from the coronal to the apical third is consistent with the observations of other studies (12-14).

In addition to apical sealing, a crucial

step in endodontic treatment is coronal sealing, which prevents microorganisms from entering the already obturated canals. This step can be achieved by using a glass ionomer cement as the base material for the coronal obturation, thereby contributing to the long-term success of endodontic treatment (15). In our study, coronal sealing was performed using a composite restoration consisting of a base filling with a resin-modified glass ionomer cement (Ionofeel F) and a light-cured composite (Charisma) for Lots I and II, providing a tight coronal seal for all samples, an aspect observed radiographically and via optical microscopy. The success of root canal obturation depends not only on the technique used but also on the methods of debridement and disinfection of the root canals; thus, procedures for cleaning and decontaminating the canals are essential for ensuring an optimal environment for obturation, preventing the subsequent development of periapical infections (16, 17). In the study, an identical irrigation protocol was applied for Lots I and II and consisted of using 5 mL of 5.25% NaOCl, sonic endoactivation for 60 seconds to enhance the irrigate, followed by a final irrigation with 5 mL of 20% EDTA solution for 1 minute per irrigation. The 1-minute duration is necessary for the irrigants to soften the dentin walls. However, uneven surfaces could promote bacterial colonization and biofilm formation (18, 19).

Furthermore, in the root canal preparation process, the shaping technique used plays a very important role in ensuring an effective endodontic obturation. In the present study, the crown-down technique was used for canal shaping, employing rotary files adapted to an endomotor. This allows for progressive cleaning from the coronal to the apical direction, facilitating the removal of dentin debris and microorganisms (20, 21).

Limitations of the study include it's in vitro nature, which does not fully replicate clinical conditions (masticatory pressure, saliva, biological tissue response), the sample size, and the exclusive use of optical microscopy for evaluation. The integration of additional methods, such as SEM or micro-CT, could provide more detailed information about the fit of the filling materials (22, 23, 24).

Furthermore, the study's results confirm that the vertical hot condensation technique is superior to the lateral cold condensation technique in terms of the adaptation and seal of the root canal filling, reducing the risk of microleakage and ensuring a homogeneous three-dimensional filling. The choice of compaction method must be guided by the characteristics of the root canal and the need to achieve optimal seal integrity, which is essential for the long-term success of endodontic treatment.

CONCLUSIONS

Vertical hot condensation with thermoplasticized gutta-percha provided superior sealing and a better fit to the root walls, particularly in the apical third, reducing the risk of microleakage. The cold lateral condensation resulted in larger marginal voids and uneven distribution of gutta-percha, indicating an increased risk of microleakage. The size of marginal distribution increased progressively from the coronal to the apical third, suggesting greater difficulties in apical sealing. The coronal sealing was achieved through coronal sealing with adhesive materials (resin - modified glass ionomer cement and light - cured composite), providing an effective seal confirmed

radiographically and microscopically. Vertical hot condensation, using thermoplasticized gutta-percha and an epoxy resin-based sealer, is the optimal method for the long-term success of endodontic treatment. Microscopic and statistical results underscore the necessity of thermoplastic techniques for achieving homogeneous and airtight three-dimensional obturations.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest and they received no specific funding regarding this scientific research.

EXPERIMENTAL EVALUATION OF THE ACTION OF ETHEPHON AND SODIUM SELENITE ON SOME HEMATOLOGICAL PARAMETERS IN RATS **(**Abstract): Ethephon (2-chloroethylphosphonic acid) is one of the most intensely used plant growth regulators. **Aim**: Assessment of hematological parameters during subacute intoxication with ethephon (200 mg/kg bw/day) in rats and evaluation of the potential protective effect of selenium (1 mg/kg bw/day) (administered as sodium selenite) in rats during the experimental intoxication by oral route with high doses of ethephon (200 mg/kg bw/day). **Material and methods:** Male Wistar rats were randomly assigned to four groups: Control group, Ethephon group (200 mg ethephon/kg bw/day, 14 days), Selenium group (1 mg Se/kg bw/day, 14 days), Selenium+ethephon group (200 mg ethephon/kg bw/day and 1 mg Se/kg bw/day). Blood samples were collected on the 15th day and a complete blood count was conducted by using an automated hematology analyzer. **Results**: Mean red blood cell count was $7.06x10^6$/µl in the Ethephon group and $7.18x10^6$/µl in the Selenium group, as compared to $7.16x10^6$/µl in the Control group. Platelet count decreased from $1028.66x10^3$/µl in the Control group to $999.66x10^3$/µl in the Ethephon group. Total leukocyte count was $7.82x10^3$/µl in the Ethephon group and $8.40x10^3$/µl in the Selenium+ethephon group, as compared to a mean of $8.07x10^3$/µl in the Control group. **Conclusions**: The modification of some of the hematological parameters in the groups to which ethephon was administered can be suggestive of the harmful effect of this substance (which is present as a residue in food products) on consumer health. Orally administered selenium (as sodium selenite) at a dose of 1 mg Se/kg bw, seems to have acted as a toxic and not as a protective agent during the intoxication with ethephon. **Keywords**: ETHEPHON, PLANT GROWTH REGULATOR, SELENIUM, HEMATOLOGICAL PARAMETER.

Ethephon (2-chloroethylphosphonic acid) (fig. 1) is one of the most intensely used plant growth regulators, due to its wide action spectrum (1).

In pomiculture and vegetable growing, ethephon can be used to hurry up flower formation, ripening or coloring of fruits, etc. (2, 3). Ethephon is also used as a treatment for cereals, to increase their mechanical resistance, by shortening and

hardening the straw (4). In some countries, ethephon is extensively used for post-harvest acceleration of ripening of bananas and mango fruits (5).

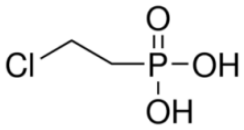

Fig. 1. Chemical structure of ethephon

In practice, ethephon is mainly formulated as solutions in concentrations between 20 and 720 g/L and is marketed under multiple brands, which correspond to specific uses. Formulations which have ethephon as active substance are registered in more than 60 countries worldwide (6, 7). The mechanism of action is because it is easily absorbed by plants and transformed in ethylene (the main metabolite), which is a natural hormone for plants (8).

In case of oral administration to laboratory animals (rats and mice), ethephon can induce digestive manifestations (gastroenteritis, gastric necrosis), respiratory and renal diseases, cardiac fibrosis, brain damage (mineralization processes) and liver damage (necrotic hepatitis). Ethephon is also teratogenic (9, 10). Other authors (11, 12) reported for ethephon direct cholinergic effects and indirect effects on the contraction of intestinal musculature. El-Okazy (13) demonstrated that ethephon perturbs some hematological and biochemical parameters in laboratory animals.

Selenium is an important biological antioxidant, because it is a constituent of glutathione peroxidase, the selenoenzyme that catalyzes the reduction of lipid peroxides and hydrogen peroxide, thus preventing the harmful effects of lipid peroxidation and protecting erythrocytes from hemolysis; in addition, selenium protects cells and cell membranes from oxidative processes (14, 15, 16).

The aim of this study was: a) to assess the hematological parameters during subacute ethephon poisoning (200 mg/kg bw/day) in rats and b) to evaluate the potential protective effect of selenium (1 mg/kg bw/day, administered as sodium selenite) in rats during experimental poisoning by oral route with high ethephon doses (200 mg/kg bw/day).

MATERIAL AND METHODS

Sodium selenite (purity 99%; CAS 10102-18-8) and ethephon (purity 96%; CAS 16672-87-0) were purchased from Sigma Aldrich. All other reagents were of analytical grade.

The animal study protocol was approved by the Research ethics committee of "Grigore T. Popa" University of Medicine and Pharmacy Iaşi, Romania. All procedures were conducted according to the 86/609/EEC directive and internal regulations of the university.

Male Wistar rats purchased from the "Cantacuzino" National Institute for Research and Development in Microbiology and Immunology were used. The animals were housed in collective cages, in relative constant environmental conditions (temperature 18-22°C; light-dark cycle: 12 hours/12 hours) and were given standard feed for rats and water *ad libitum*.

Rats, weighing 180-230 g, were randomly assigned to 4 groups of 6 animals each, to which the following treatments were given by gavage after 12 hours of fasting: Control group (C) - physiological saline; Ethephon group (ETH) - ethephon 200 mg/kg bw/day as aqueous solution; Selenium+ethephon group (SE+ETH) -

ethephon 200 mg/kg bw/day as aqueous solution and selenium 1 mg/kg bw/day as sodium selenite aqueous solution; Selenium group (SE) - selenium 1 mg/kg bw/day as sodium selenite aqueous solution.

All animals were weighed again on the 15th day, after which they were anesthetized with intraperitoneally administered ketamine (100 mg/kg bw, as injectable solution for veterinary use). Blood samples were collected in vacutainers containing anticoagulant (K_2EDTA). A complete blood count was performed by using a Sysmex XT 1800 (Sysmex Corporation, USA) automated hematology analyzer. The experimental data were processed by using *Microsoft Excel* 2013 with Data analysis add-on. A paired Student's t-test was used ($p < 0.05$ was considered significant).

RESULTS AND DISCUSSION

The results obtained for the erythrocyte count (RBC) (fig. 2) show that in animals treated with ethephon the mean RBC was slightly lower ($p = 0.398$) than in the Control group (C). An insignificant increase in mean RBC was seen in the Selenium group when compared to the Control group ($p = 0.882$). At the same time, in the Selenium+ethephon group mean RBC was slightly higher than that recorded in the Ethephon group ($p = 0.611$), but much lower than in the Control group ($p = 0.830$).

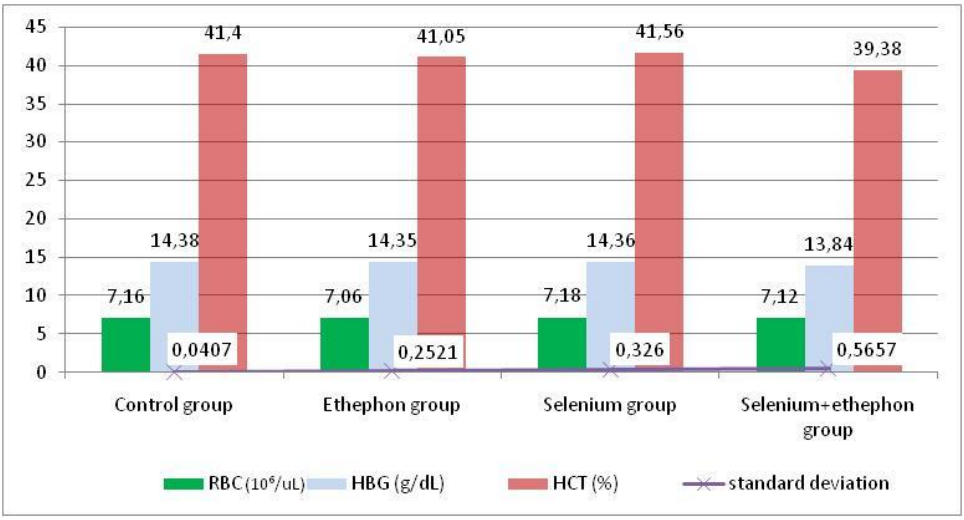

Fig. 2. Mean levels of red blood cell count (RBC), hemoglobin concentration (HBG) and hematocrit (HCT)

Hemoglobin concentration (HBG) and hematocrit (HCT) are parameters on which the investigation related to the quality of erythropoiesis is based on. Thus, mean HBG level (fig. 2) for the group treated with ethephon was almost like that for the control group ($p=0.923$). After comparing the levels recorded for the group treated with selenium and ethephon, for which the mean value was 13.84 g/dL, with those obtained for the group treated with selenium alone (mean value 14.36 g/dL) a slight decrease in mean HBG was noticed ($p= 0.451$). The results obtained from this experimental study agree

with those reported by Al-Fartosi (16), who highlighted a decrease in HBG in the animal groups treated with ethephon. For the group treated with selenium, the decrease of mean HBG and of other parameters that characterize the process of erythropoiesis is in total agreement with the results obtained by other authors (17, 18), who assessed the action of sodium selenite on hematological parameters in rats. El-Okazy (13) reported that no significant variations in HBG ($p>0.05$) were observed at low doses of ethephon; the decrease was significant when the doses were increased ($p<0.01$). Also, the RBC decreased, in correlation with the dose of ethephon ingested by the animals.

Regarding HCT, parameter which expresses the volume percentage of red blood cells in blood (fig. 2), the mean levels were in accordance with mean HBG concentrations; thus, mean HCT for the Ethephon group was slightly decreased when compared with the Control group, but without statistical significance ($p>0.05$). In the case of the group to which ethephon was administered together with sodium selenite, mean HBG was insignificantly lower when compared to the Selenium group ($p=0.508$) and Control group ($p= 0.161$). This evolution, in direct correlation with the variation of mean HGB levels suggests a reduced interference of ethephon and/or selenium with the erythropoiesis process in rats.

After analyzing the data obtained for erythrocyte indices (tab. I), very low group variations have been recorded, in accordance with the other erythrocyte indices; thus, mean corpuscular volume (MCV) and mean corpuscular hemoglobin (MCH) for the groups treated with an association of selenium and ethephon were lower than those for the Ethephon and Selenium group, respectively ($p<0.05$), and lower than those obtained in the Control group ($p>0.05$). Mean corpuscular hemoglobin concentration (MCHC) and red cell distribution width (RDW-SD) did not show statistically significant differences between groups ($p>0.05$).

The data obtained by us are generally in agreement with those reported in the scientific literature. Thus, Al-Fartosi (16) reported that sodium selenite reduces erythrocyte levels and hemoglobin concentrations in a dose dependent manner. This evolution of erythrocyte count and hemoglobin concentration was confirmed by other authors (18). In addition, Jia et al (19) confirmed that sodium selenite administered to rats in a sub chronic experiment led to a dose dependent decrease in red blood cell counts and hemoglobin concentration. The mechanism by which selenite reduces the RBC may be hemolysis, which leads to depletion of circulating red blood cells (18).

TABLE I

Values of erythrocyte indices

Group	MCV (fL)			MCH (pg)			MCHC (g/dL)			RDW-SD (fL)		
	min	max	mean	min	max	mean	min	max	mean	min	max	mean
Control	57.30	58.10	57.63	20.10	20.70	20.36	34.90	35.40	35.2	31.00	31.00	31.00
Ethephon	56.30	61.00	58.10	19.50	21.00	20.30	34.40	35.70	34.96	30.70	34.00	32.26
Selenium	56.00	59.50	58.46	19.10	21.20	20.51	34.20	35.50	34.86	29.70	32.40	31.50
SE+ETH	53.20	56.80	55.32	18.80	19.90	19.42	34.60	36.70	35.12	29.40	31.90	30.45

MCV = mean corpuscular volume; MCH = mean corpuscular hemoglobin;
MCHC = mean corpuscular hemoglobin concentration; RDW = red cell distribution width;

Platelets are anucleate cytoplasmic fragments, rich in granules, involved in hemostasis and in the initiation of tissue repair processes and vasoconstriction after vascular lesions and during inflammatory processes. Our research showed that mean platelet count (PLT) for the group treated with ethephon (tab. II) was significantly decreased when compared to the Control group (p=0.050). For the group treated with selenium, mean PLT was decreased in comparison with both the Control group (p >0.05) and Ethephon group, but the decrease was not statistically significant. Platelet count for the group treated simultaneously with Ethephon and sodium selenite was higher compared with the Selenium group, without approaching the levels recorded in the Control and Ethephon groups, respectively; in both cases, the drop in mean PLT was statistically insignificant (p>0.05).

Platelet indices, mean platelet volume (MPV), respectively, which indicates the variations in platelet volume, and platelet distribution width (PDW), which indicates the uniformity in size of platelets, are very useful for the differential diagnostic of thrombocytopenia (tab. II). The Control group had a mean MPV value of 6.96 fL and a dispersion of values given by a standard deviation of 0.294. For the other three groups, the mean values are higher than those observed for the Control group; for the association ethephon-selenium the value was significantly decreased when compared to the Selenium group (p=0.003), but increased in comparison with the Control group (p=0.023). These results are in accordance with the data published by El-Okazy (13), who reported that ethephon altered the hematopoiesis process, depending on the dose, exposure period and animal species. The results obtained for PDW, which reflects the variation in platelet size, correlated with the distribution of PLT values and with the percentage of macro thrombocytes (P-LCR), respectively (tab. II). The increase in mean PDW values was statistically significant when compared to the Control group, both in the ethephon group and in the Selenium group (p=0.029 and p=0.004, respectively). In the group treated with an association of selenium and ethephon, PDW decreased significantly (p=0.021), when compared to the group treated with selenium alone, but it did not reach the levels in the control group.

TABLE II

Mean values for platelet count and for thrombocytes indices

Group	PLT (x10^3/ µL)			MPV (fL)			PDW (fL)			P-LCR (%)		
	min	max	mean	min	max	mean	min	max	mean	min	max	mean
Control	939	1103	1028.66	6.50	7.30	6.96	7.10	7.70	7.40	4.90	6.90	5.75
Ethephon	847	1118	999.16	7.10	7.50	7.33	7.50	8.00	7.78	6.00	8.90	7.66
Selenium	697	1006	930.83	7.40	9.30	8.53	7.60	10.5	9.46	7.70	18.40	15.00
SE+ETH	848	1146	964.85	7.00	7.90	7.45	7.20	8.80	7.92	5.60	11.20	8.21

PLT = platelet count; MPV = mean platelet volume; PDW = platelet distribution width; P-LCR = platelet large cell ratio;

An increase in the percentage of macrotrombocytes was observed in all groups, in comparison to the Control group, but especially in the group treated with selenium; the increase was statistically significant for all groups, but especially for the group

treated with selenium ($p > 0.05$). These results would suggest an influence of selenium at the doses administered to rats on the process of hemostasis, by increasing the percentage of macrotrombocytes.

White blood cells (WBC) are involved in the immune defense processes of the body. Depending on their structure, leukocytes are classified in granulocytes or polymorphonuclear leukocytes (neutrophils, eosinophils and basophils) and agranulocytes or mononuclear leukocytes (lymphocytes and monocytes). Their role is complex and different, depending on their type. In our research, the mean values of total WBC count (tab. III) for the Ethephon and Selenium groups are very near, but slightly decreased in comparison to the Control group ($p>0.05$ for both groups). Conversely, a statistically insignificant increase was observed in WBC for the Selenium-ethephon group ($p>0.05$) when compared to the Control, Ethephon and Selenium groups. The mean values for this parameter are suggestive for the intervention of ethephon, but also of selenium (administered as sodium selenite) as xenobiotics, intervention manifest through the alteration of the leukocytic formula.

The results obtained in this experimental study are in contradiction with those reported by El-Okazy (13), who found that WBC showed a significant, dose dependent increase ($p < 0.01$) in the groups treated with ethephon, when compared to the Control group. Pisek et al. (20) confirmed the dose dependent reduction of WBC in laboratory animals after administering sodium selenite, a phenomenon which was also observed during our research. Sadeghian et al. (21) suggested that when administering selenium in supranutritional, but subtoxic doses in sheep, the WBC does not vary or barely increases; the explanation could be the antioxidant properties of selenium and its protective effects towards oxidative stress. Other authors (22) reported that selenium at oral doses of 1 mg/kg bw, administered to mice for 10 days, slightly increased WBC.

Basophils were detected only in the Selenium and in the Selenium+ethephon groups (tab. III), suggesting that their occurrence is due exclusively to selenium. For the groups treated with ethephon, respectively selenium, the mean values are lower than those observed for the Control group ($p<0.05$). On the other hand, in case of the Selenium+ethephon group, the mean value is approximately 70% higher when compared to the Ethephon group and 64.5% higher when compared to the Selenium group. In both cases, the increase is not significant ($p>0.05$). These results would suggest that the association of selenium with ethephon tends to normalize the decrease in eosinophils determined by the two substances, administered individually. Our results are in accordance with those reported by Aghwan (23), who highlights the role of selenium, in low doses, in normalizing the hematological parameters in laboratory animals.

Lymphocytes are mononucleate cells with role in antibody systems and immunological reactions. The number of lymphocytes is an easily accessible parameter for examining the potential immunotoxic chemical substances. Within our current research, the mean percentage of lymphocytes (fig. 3) for the groups treated with ethephon, respectively with selenium, are higher than those observed for the Control group. In both cases, the increase is statistically significant ($p<0.05$). The percentage of lymphocytes for the group treated with ethephon and selenium is lower than that for the Selenium group

($p>0.05$). According to a study conducted on mice, Wang et al (24) reported that for the group treated with a dose of 47.7 mg ethephon/kg bw/day, the percentage of lymphocytes from peripheral blood rose by 37% and in the group treated with 143 mg ethephon/kg bw/day, the increase was 54%.

Surprisingly, the percentage of lymphocytes from the total number of white blood cells from blood did not show any difference between the Control group and the groups treated with ethephon. This means that not only the lymphocyte count rose, but also the number of granulocytes. It could be suggested that ethephon may also influence all nucleate cells from blood.

TABLE III

Mean WBC levels

Group	WBC (10^3/ µL)			W-LCC (x10^3/ µL)			Baso (%)			EO (%)			W-LCR (%)		
	Min	max	Mean	min	max	mean	Min	Max	Mean	Min	Max	Mean	Min	Max	Mean
Control	8.03	8.13	8.07	1.12	1.63	1.32	0	0	0	0.50	1.41	0.86	16.51	20.12	17.46
Ethephon	6.85	8.91	7.82	0.80	1.76	1.15	0	0	0	0.10	0.63	0.30	10.00	19.80	14.76
Selenium	7.86	8.23	8.01	1.15	1.57	1.30	0	0.10	0.030	0.10	0.50	0.31	13.91	19.12	15.20
Selenium+ ethephon	5.84	10.61	8.40	1.10	2.75	1.60	0	0.01	0.004	0.10	2.12	0.51	10.40	28.50	19.34

WBC = white blood cell (leukocyte) count; W-LCC = white large cell count; Baso = basophils;EO = eosinophils;

Monocytes are white blood cells with the capacity of phagocytosis; they are formed in the bone marrow, they reach the blood stream and invade various tissues during an infectious process. Mean monocyte counts (fig. 4) are practically identical for the Ethephon and Selenium+ethephon groups and slightly decreased compared with the Control or Selenium group ($p>0.05$ for all groups).

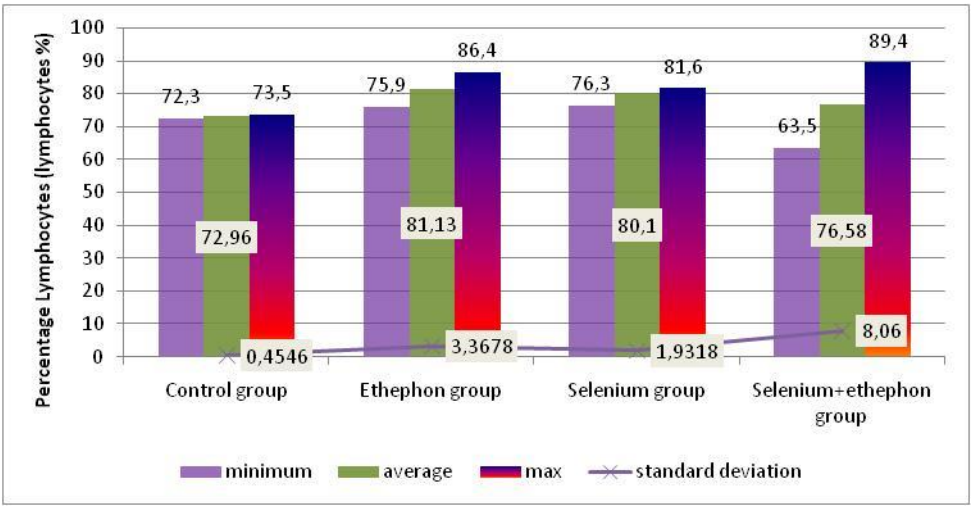

Fig. 3. Percentages of lymphocytes in the experimental groups

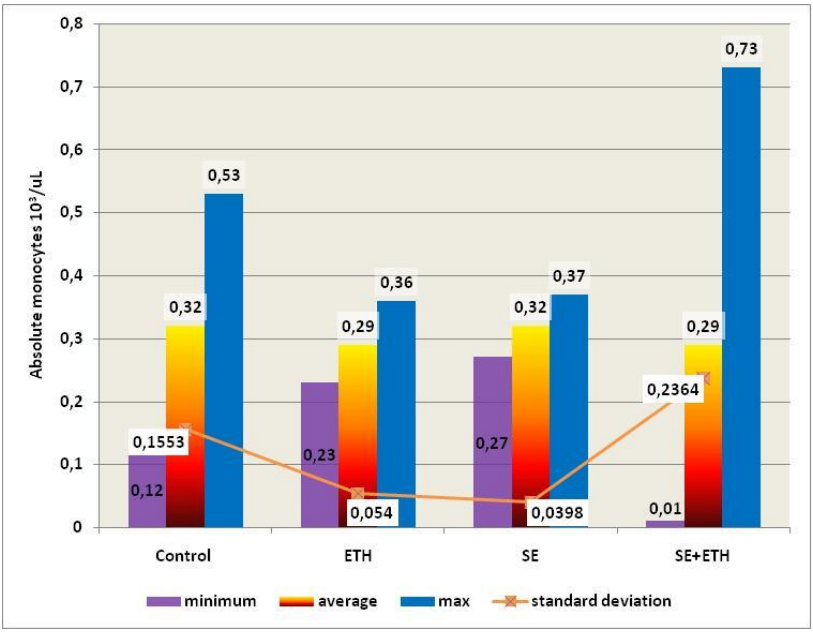

Fig. 4. Monocyte count for the experimental groups

CONCLUSIONS

The results of this study highlighted the effects of orally administered ethephon on hematological parameters in rats; the changes in the values of some complete full blood count parameters in the groups treated with ethephon may be suggestive of the harmful effect on consumer health of this plant growth regulator, present as a residue in food products. Selenium, administered orally as sodium selenite, at a dose of 1 mg/kg bw, seems to have acted as a toxic and not as a protective agent during ethephon poisoning.

AN OVERVIEW ON SCREENING FOR BREAST CANCER AWARENESS IN ROMANIAN GENERAL POPULATION **(**Abstract): Trends in breast cancer incidence has been decreasing worldwide since several years, meanwhile screening programs were properly implemented in countries with financial support for healthcare infrastructure and population awareness to choose prevention. **The study aim** was to evaluate the level of knowledge regarding risk factors and screening for breast cancer in general population from Romania. **Material and methods**: The study was conducted on a group of 470 individuals aged between 21 and 55, during 1st October and 31st November 2016. The study was based on fulfilling an online questionnaire of 20 items, sent by e-mail. **Results:** Participants chose "breastfeeding" as a protective factor (84.47%), "family history" as a risk factor (78.09%), lobular carcinoma *in situ* as precancerous lesion (20.00%), mammography as a screening method (94.04%), performed "once a year in 45-54 aged women" (90.21%). A breast screening program would be useful in Romania because of the "high incidence" (98.30%) for "early detection of the disease" (97.87%), and nothing could deter people from screening participation (84.34%), but "fear of detecting a cancer" (12.64%). **Conclusions**: A larger study on a representative population group would provide better information and could be a capable guidance for national strategies on breast cancer prevention and screening. **Keywords**: BREAST CANCER, SCREENING, PREVENTION, QUALITY OF LIFE, QUESTIONNAIRE.

Readers of a paper on such a common topic for our decade as breast cancer are usually accustomed with an introduction about prevalence and mortality, as well as risk factors or an overview on screening programs worldwide. Same as responders below, we chose to skip them and took into consideration some information regarding healthcare systems and indices performed by worldwide professionals, just because of the quality the above-mentioned notions depend on.

By the year 2000, Romania ranked 99th amongst world healthcare systems (1). Many countries have recently introduced reforms in the healthcare sector with the

explicit purpose of improving their performance. There is an extensive literature on healthcare system reform and recent debates on the best way to measure performance so that the impact of reforms can be assessed. The performance of a healthcare system has been a major concern for decision-makers over many years. Performance measurement requires an explicit framework that defines the objectives of a healthcare system, on which performance can be evaluated and quantified. To assess overall effectiveness, the first step was to combine individual achievements with all five health system targets into a single number, called the composite index. The composite index is an average of the objectives of the five components, reaching the country in all five indicators such as health, health inequality, response, reactivity-distribution and fair financing (2).

One of the recently introduced indicators for assessing the state of development of a country is *Human Development Index* (HDI). This indicator considers that factors such as the health and educational level of the population are intangible objectives of population development, but not instrumental assessment purposes. The composite index is based on a similar idea, measuring the overall achievement of the intrinsic goals of the healthcare system (2).

An indicator developed by the research group involved in the *Global Burden of Disease Study* 2015 (GBD 2015) is the *Healthcare Access and Quality Index* (HAQ). It has been found that in the past two decades, in almost all regions of the globe; the values of this index have increased, ranging from 28.6 to 94.6. Thus, varied patterns appeared in regions and degrees of development, depending on the type of specific pathology. For example, oncologic pathology for developed countries has influenced HAQ values. In countries with medium levels of development, there are kidney coronary diseases, diabetes, diarrheal diseases and lower respiratory infections, but measles and tetanus in less developed countries. The authors of the study showed that if every country had reached the development average, then the overall HAQ would have reached 73 (out of 100 maximum) in 2015 (2-4).

Breast cancer is the most common cancer in women with a second-place frequency in oncologic pathology and more than 1.6 million new cases diagnosed in 2012, affecting women in all regions of the globe with any level of economic development. The lowest incidence rates were recorded in West Africa and East Asia (27 per 100,000 inhabitants), and the highest in Western and North America (over 92 per 100,000 inhabitants). Breast cancer is the most common cause of death by oncology pathology in women in developing regions (14.3% of total), and in the developed ones, the second place after lung cancer (15.4% of the total) (5, 6). In this context, screening programs for early detection of breast masses and population awareness about screening principles and methods should be considered.

The study aim was to evaluate the level of awareness regarding risk factors and screening for breast cancer in general population of Romania.

MATERIAL AND METHODS

The study was conducted on a group of 470 individuals aged between 21 and 55, during 1st October and 31st November 2016. The study was based on an online questionnaire of 20 items, sent by e-mail.

The applied questionnaire was based on models of WHO and CDC, Romanian versions. The inclusion criteria were both males and females, from general population of Romania. The exclusion criteria were graduation from medical schools, colleges and universities. All patients were informed about the confidentiality and privacy of data. The data were processed using *MS Excel 2010.*

RESULTS

1. Questions 1-5:

Demographic characteristics

The demographic structure of questioned group highlighted that most of participants were young adults (26-30 years old-35.53%) and women (77.45%), from urban area (79.46%), graduated from a university (41.06%) and employed (84.26%) (tab. I, fig. 1).

TABLE I.

Demographic and socioeconomic characteristics (n=470)

Characteristics	Frequency %
Age (years)	
21-25	24.89
26-30	35.53
31-35	28.30
36-40	6.17
41-45	2.77
46-50	2.13
51-55	0.21
Gender	
Female	77.45 (n=364)
Male	22.55 (n=106)
Residence area	
Urban	79.36
Rural	20.64
Education	
Primary	1.7
Secondary	37.02
University	41.06
Post-university	20.21
Occupation	
Employee	84.26
Student	9.57
Unemployed	6.17

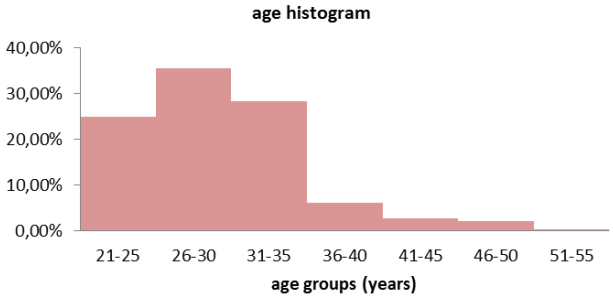

Fig. 1. Age histogram

2. Questions 6-11:

Breast cancer awareness

Item 6: "Protective factor in breast cancer". Most of the participants chose the variant "breastfeeding" (84.47%), but there were people who believed that "smoking" (11.06%) or "overweight" (2.34%) or even "alcohol consumption" (2.13%) could protect against breast cancer in women. *Item 7*: "Risk factor in breast cancer". 78.09% of responders ticked "family history of breast cancer", but 19.57% considered that "breast implants" could be a risk factor, or even "physical activity" (1.7%). *Item 8*: "Premalignant lesions". Responders thought that breast cysts (62.34%), lobular carcinoma *in situ* (20.00%) or mastitis (13.40%) became malignant. Lipoma was ticked by 4.26% only. *Item 9*: "Symptoms of breast cancer". Participants answered, "nipple retraction" as a sign in 46.38%, then "fatigue" in 45.74%. "Nausea" or "weight gain" chose by < 5% of the study group. *Item 10*: "Breast changes". 59.15% chose "orange peel", but other 20.00% ticked "pain before and after menstruation", but "decreasing" (19.57%) or even "increasing" (1.28%) in breast volume. *Item 11*: "First degree relatives with breast cancer". Answers were *no* for most of the participants (93.62%), but 6.38% of total did (tab. II).

TABLE II.

Protective & risk factors. Premalignant lesions *(correct answers only)*

Items	%
Protective factor	
breastfeeding	84.47
Risk factor	
family history of breast cancer	78.09
Premalignant lesions	
lobular carcinoma *in situ*	20.00
Symptoms	
nipple retraction	46.38
fatigue	45.74
Breast changes	
orange peel	59.15

3. Questions 12-20:

Breast cancer screening awareness

Item 12: "Breast screening methods". Most of participants answered mammography (94.04%), but 5.11% chose "computed tomography". Few of them chose "endoscopy" (0.64%) and even "colposcopy" (0.43%). *Item 13*: "Clinical exam in 20-20 aged women". "Once a year" was the most ticked variant (67.87%), but 19.79% chose "two-yearly", 6.81% - "triennially", 5.53% - "quinquennially". *Item 14*: "Mammography in 45-54 aged women". "Once a year" for 90.21% of participants, but 7.02% - "two-yearly", 1.91% - "triennially", 0.85% - "quinquennially". *Item 15*: "Self-examination". Rarer than "once a year" - 44.51% of women involved in questionnaire, "twice a year" – 28.02%. *Item 16*: "Screening purpose". Most of responders (97.87%) believed in "early detection of a cancer", but there are people (0.43%) who chose "mutilating surgical treatment" or "little purpose". *Item 17*: "Necessity of screening program in Romania". Most of participants answered, "yes because the incidence is very high" (98.30%), but few thought that "it isn't, because it could not influence women health" or "Romania has other priorities" (0.85%). *Item 18*: "Deterring from screening participation". 84.34% believed that "nothing, it is useful for health monitoring". 12.64% had "fear of detecting a cancer", 1.92% "fear of doctor" or "waste of time, it cannot help". *Item 19*: "Choosing prophylactic mastectomy". "Most of participants chose "yes" (84.89%) and the others "no" (15.11%). *Item 20*: "Frequency of breast cancer in Romania". A half of responders chose "frequent" (50.00%) and the most frequent cancer in women (46.17%), but few answered "rare" (3.62%) or "not at all" (0.21%) (tab. III).

TABLE III.

Breast cancer screening awareness (*correct answers only***)**

Items	%
Breast screening methods	
mammography	94.04
Mammography in 45-54 aged women	
once a year	90.21
Screening purpose	
early detection	97.87
Necessity of screening program in Romania	
yes, because the incidence is very high	98.30
Deterring from screening participation	
nothing, it is useful for health monitoring	84.34

DISCUSSION

Austria was the first EU state member state which implemented a breast cancer screening program, in 1974. At that time, screening programs for breast cancer were appropriate in many European countries, with mammography being indicated in women over the age of 40, however, with-

out two incidents. Other countries included in screening programs only women with medical insurance. Sweden was one of the first European countries which managed breast screening programs with a high performance on national level. Women aged 50-69 are recommended for biannual mammograms and those of 40-49 years of age to perform mammographic tests every 18 months. In about 50% of cases, a biannual mammography is recommended for women aged 70-74 (7-9).

The European Commission has recommended screening for breast cancer in females aged 50-69 in all member states since 2003. Such active national programs, according to the European Council guidelines, were carried out in 22 states, in 2007. Various models of national screening programs, including online invitations, have been able to adapt and improve existing detecting resources and facilities, and the adaptation of protocols to the risk profile and clinical status of every woman. However, several national and European studies showed that screening participation due to online invitation achieves a higher and faster level of coverage, as well as lower costs for healthcare providers (9).

In Romania, in accordance with the Regional Oncology Institute of Iași, a local screening program is performed following algorithms depending on the age of women. For young women aged 20-40 years, self-examination is recommended monthly, then clinical consult annually. For them aged 40-50, a mammogram is recommended to be performed in two incidents for each breast, every two years. Depending on the aspect of mammography, the physician may recommend completing breast imaging investigations with mammary ultrasound and / or breast MRI. In women aged 50-70, mammogram is recommended to be perform in two incidents per breast, yearly. For young females with an oncogenetic risk, it is recommended to alternate classical mammogram with breast MRI (mammography followed by breast MRI after six months) (10).

The issue of adherence to breast screening programs plays a substantial role in every country. National healthcare services should guarantee access and participation in screening program of all eligible women, even if this would entail an increasing in healthcare costs. For this purpose, awareness and information campaigns performed in general population are needed to improve awareness of breast cancer risk factors, screening and prevention methods, as well as screening protocols. Population gets old and this fact has led to a steady increase in the incidence of oncological pathology. A well-implemented and monitored national cancer registry for every state allows monitoring the effectiveness of the fight against breast cancer, too. A breast screening national program could mean an increased diagnostic rate. Any change in such screening program active for years could also have an impact on the incidence of the disease. For example, the introduction of digital mammography in the Netherlands has led to increase values of breast cancer incidence, but mortality rates were not affected. This could be explained by the effect of increasing survival rate due to improved diagnostic methods, surgical techniques and more effective treatments (10, 11).

Statistics highlighted that participation in mammographic screening for early detection reduced breast cancer mortality by 20%. For example, in UK population, mammographic screening saved about

1,300 women yearly or the equivalent of about 22,000 years of life. However, we must also consider the negative effects that screening may have, especially the risk of over-diagnosis. Short-term screening trials show a rate of over-diagnosis higher than 10%. The excess mortality resulting from the investigation and treatment of breast cancer is insignificant and outweighed by the benefits of treatment. Other harm effects such as increased anxiety and emotional discomfort can occur frequently. In the current situation, when breast cancer treatment has improved considerably, the question that arises is whether screening would be relevant or not. We need to look at the benefits of screening independently and the benefits of improved treatments. To weigh up the benefits of screening and current treatments, there is not a reason to stop breast screening programs (12-14). Further research, including quality of life studies, will be able to answer more promptly to this issue.

Breast reconstruction after surgery for cancer is a way to improve body image, aesthetic and emotional aspects of women who experience such a disease as cancer. Studies highlighted that there is no single reconstruction procedure that could be discussed with a patient from the beginning, but a careful selection of techniques must be made, allowing for optimal results. Thus, many elements, such as incision lines, tegument or asymmetrical differences in unilateral reconstruction, should be considered (15). However, this information should not avert the patient from choosing postoperative reconstruction procedure, as a subsequent positive attitude that could contribute to increase the survival rate and improve scores in health-related quality of life (16).

Thus, the wellbeing of every woman considering breast oncologic condition safety has also a cost. In addition to increase the survival rate, by early detection and treatment, mammographic screening identifies tumor masses that would have been never detected during the woman's lifetime if she had not been ever screened. Here is the problem of over-diagnosis (12). Another eligible question is whether this improved treatment would have been necessary for the woman to extend her lifetime or she can live as well with breast tumor or even better, considering that quality of life scores change considerably in a woman who underwent surgical treatment for breast cancer.

CONCLUSIONS

As soon as the questionnaire was uploaded, we were surprised that both women and men from general population of Romania were very receptive to participate in. The responders had no proper information either about breast cancer risk factors, or screening. Many participants misinterpreted breast implants as a risk factor, claimed that fear of detecting cancer would deter them from participating in screening, refusing prophylactic mastectomy for high oncogenetic risk and having no idea about breast reconstruction after that surgical procedure.

We believe that our study is important because it provides information regarding breast cancer level of awareness in a general population of a country never ranked amongst 50th world healthcare systems. A larger study on a representative population group would provide better information and could be a capable guidance for national strategies on breast cancer prevention and screening.

LATE CERVICAL NODAL TUBERCULOSIS RECURRENCE MIMICKING METASTASIS OF PAPILLARY THYROID CARCINOMA. A CASE REPORT (Abstract): Although papillary thyroid carcinoma (PTC) represents the most usual form of thyroid neoplasia the association with cervical tuberculous lymphadenitis (CTL) is rare and diagnosis remains a challenge. **Case report**: We report the case of a 78-years-old female patient with personal history of cervical fistulizing tuberculous gumma diagnosed with right lateral cervical mass and Hashimoto nodular thyroiditis. The neck ultrasound and CT exam revealed an enlarged right thyroid lobe containing a nodule of 2/2 cm and right later cervical multiple masses resembling lymphadenopathies. The patient underwent to surgical treatment which consisted in total thyroidectomy and modified neck dissection with resection of internal right jugular vein adherent to the lymph node mass. **Results**: The final pathology report demonstrated a pT3mN0LV1Pn0 right lobe papillary thyroid carcinoma on Hashimoto thyroiditis while lymph nodes presented giant epithelioid granulomas with giant multinuclear Langhans cells and central necrosis consistent with the diagnosis of tuberculous adenitis. The postoperative course was uneventful and the patient was referred to both TB and endocrinology specialist. **Conclusions**: Cervical tuberculous lymphadenitis can mimic metastatic adenopathy in papillary thyroid carcinoma and frequently the definitive diagnosis is achieved by excisional biopsy and histopathological examination. **Keywords**: PAPILLARY THYROID CARCINOMA, CERVICAL TUBERCULOUS LYMPHADENITIS, THYROIDECTOMY, LYMPHADENECTOMY.

Papillary thyroid carcinoma (PTC) represents the most generic form of thyroid neoplasia. Total thyroidectomy eventually followed by radioiodine is the treatment of choice while cervical lymphadenectomy is performed in case of apparent or histologically proven lymph node metastases (1). On the other hand, tuberculosis (TB) remains a major health problem today. It mainly involves the lungs but can cause infection in almost all tissues in the body. Lymph node tuberculosis (LNT) is a common cause of lymphadenopathy in areas in which TB is endemic. Although new diagnostic methods have been developed, especially in patients without a history of tuberculosis, the cervical tuberculous lymphadenitis (CTL) diagnosis remains a challenge.

CASE REPORT

We report the case of a 78-years-old female patient who has been referred to our surgical unit by the endocrinologist with right lateral cervical mass and Hashimoto nodular thyroiditis. Significant elements in the history of the patient were a cervical fistulizing tuberculous gumma almost 50 yrs. ago, left mastectomy for in situ breast cancer (2014), arterial hypertension and atrial fibrillation under treatment. The physical examination revealed a good general appearance patient, of normal weight, vitals stable, apyrexial. Neck examination reveals a right lateral aspect elastic tender mass from the top of posterior triangle extending behind clavicle and palpable nodular right thyroid lobe; suprasternal scar from previous treated skin TB. Laboratory tests showed autoimmune thyroiditis (ATgAB-629 IU/ml, APOAB-446 IU/ml) with mild hypothyroidism, iron deficiency anemia. The neck ultrasound exam revealed an enlarged right thyroid lobe containing a nodule of 2/2 cm, a micronodular normal sized left lobe and right later cervical multiple masses resembling lymphadenopathies. Thyroid scintigraphy described a heterogenous goiter with hypo/affixation of the right lobe nodules and inferior pole retrosternal, right lobe is compressed by a cervical mass with no uptake of Tc. CT scan showed along right internal jugular vein- multiple cystic tumors forming a mass of 43/48/73 mm (fig 1, 2).

FNAC from the largest thyroid nodule showed a benign aspect. Chest X-Ray, abdominal ultrasonography and ENT – indirect laryngoscopy examination were all normal. Patient underwent to surgical treatment which consisted in total thyroidectomy and modified neck dissection with resection of internal right jugular vein adherent to the lymph node mass. The frozen section of lymph nodes revealed TB adenitis.

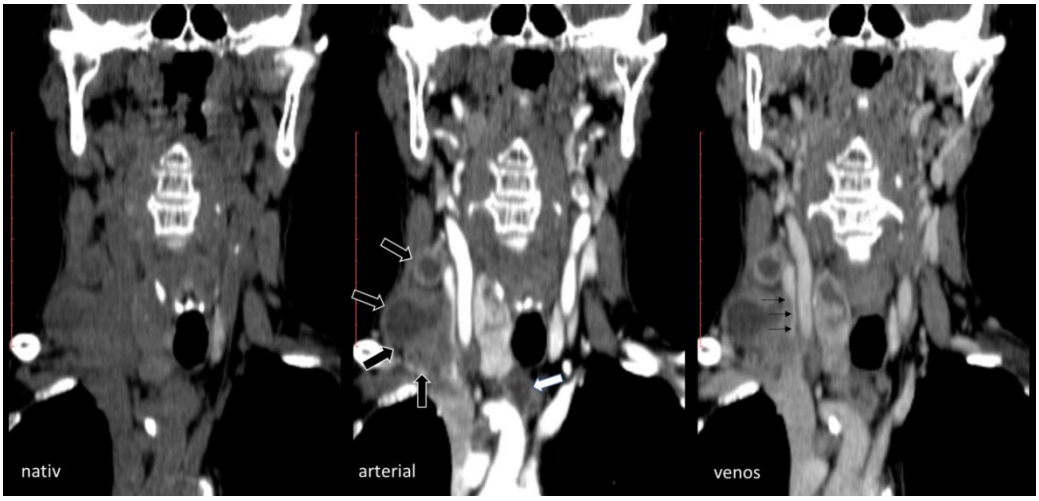

Fig. 1. Cervical coronal section: supraclavicular and right inferior jugular cystic tumors (black arrows). Similar lesion in contact with right thyroid lobe (white arrow). Compression on right jugular vein (thin arrows).

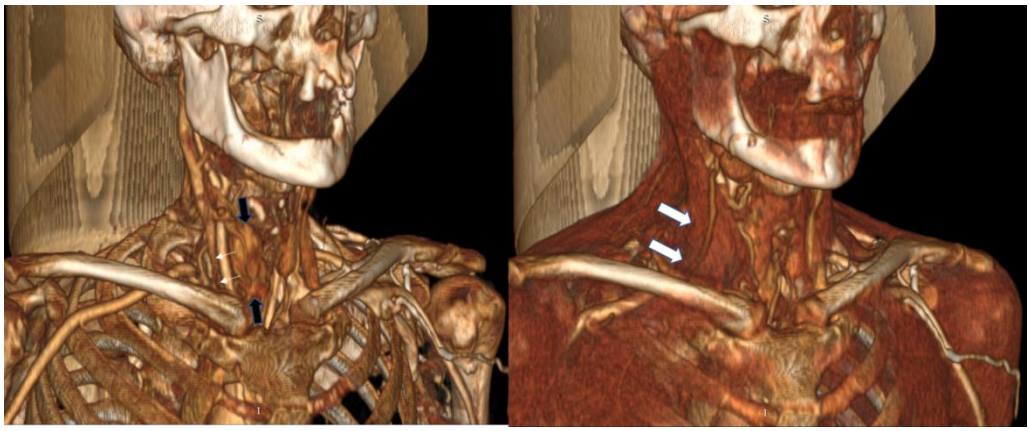

Fig. 2. 3D reconstruction – right jugular vein compression (thin white arrows), right thyroid lobe increased in volume (black arrows), jugular supraclavicular tumor mass (thick white arrows)

The final pathology report demonstrated a 2.5 cm papillary thyroid carcinoma on the right lobe and Hashimoto thyroiditis, capsular invasion (fig. 3), left lobe Hashimoto thyroiditis, all lymph nodes without tumor cells, giant epithelioid granulomas with giant multinuclear Langhans cells and central necrosis - TB adenitis (fig. 4). The staging of the tumor was pT3mN0LV1Pn0.

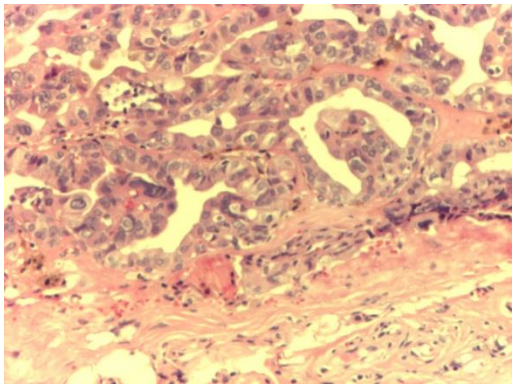

Fig. 3. Papillary thyroid carcinoma with capsular invasion, HE, x10

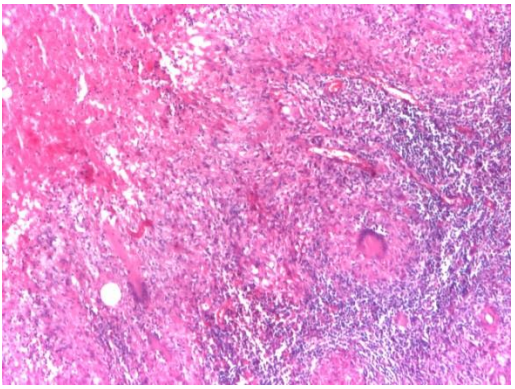

Fig. 4. Giant epithelioid granulomas and central necrosis, HE, x10

The postoperative course was uneventful and the patient was discharged in the 5th postop day and referred to both TB and endocrinology specialist.

DISCUSSION

One of the most common clinical presentation of extrapulmonary tuberculosis is cervical lymphadenitis. In a study published in 2000, Kanlikama et al. demonstrated that the history of TB contact is in only 21.8% and tuberculosis infection occurs in only 16.1% of the cases with cervical lymphadenitis (2). Cervical tuberculous lymphadenitis

may appear either a unilateral single or multiple painless mass and is usually found in the supraclavicular area (3). Partially, these clinical features are common to those of the metastatic adenopathy from PTC. The sonographic characteristics of tuberculous adenopathy are very like metastatic cervical nodes from PTC namely intranodal cystic necrosis and calcification. CT scan can be a valuable complementary test in cervical tuberculous lymphadenitis but is not sufficient to make a certain diagnosis. The most common pattern on CT is a node with main area of necrosis but in our case the features were not consistent. Fine-needle aspiration cytology could have shown a well-formed epithelioid granuloma and the presence of caseous necrosis but, again, in our case the appearance was uncertain. Coexistence of thyroid cancer and cervical tuberculous lymphadenitis is rare. However, some similar cases have been reported to date (4, 5) but preoperative diagnosis was impossible for most cases. As the other case reports, we could not distinguish preoperatively whether cervical lymph nodes enlargement was due to PTC metastasis or tuberculosis infection either by clinical findings or imaging studies.

CONCLUSIONS

In our experience, cervical tuberculous lymphadenitis can mimic metastatic adenopathy in papillary thyroid carcinoma. Preoperative diagnosis can be difficult but is valuable in avoiding unnecessary and complications prone neck dissection. In the presence of enlarged cervical lymph nodes on a patient with TB history, tuberculous lymphadenitis should be considered. The definitive diagnosis of tuberculous lymphadenitis is done by excisional biopsy and histopathologic examination if all other techniques fail.

SEPTIC COMPLICATIONS AFTER EMERGENCY SURGICAL PROCEDURES CONSENSUS OF ITALIAN SOCIETY ON TRAUMA AND EMERGENCY SURGERY (Abstract). **Background**: Emergency surgery is an independent factor among the postoperative morbidity risks. The most frequent complications after emergency abdominal surgical procedures occur in the case of digestive tract surgery and they manifest themselves as intestinal dehiscence or abdominal sepsis. Delay on recognition of one of these conditions is an important variable in the outcome. Moreover, a general agreement in this field is currently lacking, thus SICUT society designed a consensus study aimed to define their optimal workout**. Material and methods**: The electronic search was performed using the following databases Medline, PubMed, Scopus, Embase and Cochrane Library. Inclusion criteria were date of publication after 2006, and type of work randomized clinical trials and prospective, prospective observational studies, systematic reviews and meta-analysis. Papers were reviewed and selected by two experts with the help of a third in the role of tutor per the PRISMA methodology. Experts have indicated levels of evidence and grades of recommendations using the method of "*Grading of Recommendations Assessment, Development, and Evaluation"* (GRADE). **Results:** The only method of reducing the morbidity rate is to follow the septic complications of postoperative surgery, including the early diagnosis and the individual treatment following precise criteria. **Conclusions**: This consensus is in line with current international strategies and guidelines, and it could be a useful tool in the management of these postoperative complications after emergency abdominal surgery. Early recognition and multidisciplinary management of these septic complications is recommended. **Keywords:** COMPLICATIONS AFTER EMERGENCY SURGICAL PROCEDURES, MANAGEMENT OF SEPTIC COMPLICATION, EMERGENCY SURGERY, CONSENSUS.

Emergency surgery is an independent factor for postoperative morbidity risk. A recent study published on *JAMA Surgery* highlighted 7 emergency surgery at greater risk, involving, almost exclusively, the intestinal disease and in which the main complication is constituted by intestinal dehiscence or abdominal sepsis (1). Delay on recognition of one of these conditions is an important variable in the outcome (2). The symptoms and signs associated with postoperative abdominal sepsis can be

subtle and/or difficult to recognize in a critical patient with a complex clinical course, so our goal was the definition of a clinical pathway that leads to early control of septic source.

MATERIAL AND METHODS

The electronic search was performed using the following databases Medline, PubMed, Scopus, Embase and Cochrane Library. Research keywords were: emergency surgery, acute care surgery, abdominal sepsis, anastomotic leek, abdominal abscesses and peritonitis. Inclusion criteria were date of publication after 2006, and type of work randomized clinical trials and prospective, prospective observational studies, systematic reviews and meta-analysis.

Papers were reviewed and selected by two experts with the help of a third in the role of tutor per the PRISMA methodology. Our research produced 1,446 articles from which 621 were included for review. Experts have indicated levels of evidence and grades of recommendations using the method of *"Grading of Recommendations Assessment, development, and Evaluation"* (GRADE) (3) under assessment by the members of ITALIAN SOCIETY ON TRAUMA AND EMERGENCY SURGERY (SICUT) and revision of two experts appointed by the Board of SICUT.

RESULTS

The first step was to define the terminology.

Secondary peritonitis is defined as an acute infection of the peritoneum due to loss of integrity of the gastrointestinal tract (SP) are spontaneous perforations (e.g., due to diverticulitis, appendicitis, cholecystitis) traumatic perforation of a visceral organ, or iatrogenic causes (e.g., perforation, anastomotic leek).

Tertiary peritonitis (TP) is an uncommon disease in comparison with secondary and primary ones. It is defined as a severe recurrent as persistent intra-abdominal infection after apparently successful and adequate surgical source control of secondary peritonitis. In approximately 80% of the patients with SP, the initial surgical intervention may sanitize the abdominal cavity from the septic source (4, 5). The remaining patients develop a persisting peritonitis characterized by a prolonged systematic inflammation and organ dysfunction leading to high rate of SIRS, sepsis, severe sepsis, or septic shock. TP usually occurs in ICU settings at least 48-72 hours following surgical adequate intervention for SP (6). Thus, mortality of TP ranges between 30% and 64%. The latest ICU consensus conferences guideline provides a precise definition of TP as intra-abdominal infection that persists or recurs ≥ 48 hours following successful and adequate surgical source control. This definition contains two essential conditions, which should be met: ***the time period ≥ 48 hours and the successful surgical source control (6)*** (GoR A).

Abdominal abscesses may be visceral and non-visceral, intra or extraperitoneal. Non-visceral abscesses arise after resolution of diffuse peritonitis in which a loculated area of infection and suppuration is ~walled off~ and persists, or after a perforation of a viscerus (or an intestinal anastomosis) that is effectively localized by peritoneal defenses.

The definition of **anastomotic leakage (AL)** is widely agreed as a breach in a surgical joint between two hollow viscera, with or without active leak of luminal contents (although there are some minor deri-

vations (7). The definition of AL adopted the classification that was proposed by the International Study Group of Rectal Cancer. The severity of AL was classified into three grades according to the following criteria:

- grade A, AL requiring no active therapeutic intervention,
- grade B, AL requiring active therapeutic intervention without relaparotomy,
- grade C, AL requiring relaparotomy.

On the basis of this study SICUT experts answered the following questions and authored a guide for good practice:

1. What clinical and biological indicators can be used to suspect the early onset of a complication in the presence of a suboptimal clinical course and with devious clinical signs without no obvious condition of sepsis or leakage of enteric juices through the abdominal drainage?

Statement A: The most reliable biological indicators to evaluate the occurrence of major abdominal septic complication are the increase and trend of PCR and/or procalcitonin between the 3rd and the 5th postoperative day (GoR C**)** (8-11).

Statement B: The combination of a postoperative modification of Mannheim Peritonitis Index and Apache II is an indicator of risk of septic complication (GoR C) (12). The mean Mannheim Peritonitis Index (MPI), which was recorded at the revealed significant higher values for TP patients compared to SP patients (4) (GoR A).

Marshall score is more suitable for SP. The sum score of the APACHE II and MPI presented an increased percentage of sensitivity (77%) compared to isolated APACHE II and MPI. Both prognostic scores were statistically correlated to mortality and tertiary peritonitis (GoR C) (12). Indicators to assess: New Definition Sepsis (Quick Sofa Score and Lactates), DULK Score and Early Warning Score (13, 14).

2. What is the indication and the role of computed tomography (CT) in the early diagnosis of postoperative sepsis where there is not an obvious clinical condition of dehiscence or peritonitis?

Statement A: In adult patients not undergoing immediate laparotomy, CT scan is the imaging modality of choice to determinate the presence of an intra-abdominal infections and its source (GoR B).

Statement B: The indication for CT scan is determined by the onset of abdominal symptoms associated with the changes of clinical and biological indicators referred to in paragraph 1 so it is recommended within 24 hours of the onset of these changes (GoR B).

3. Once the septic complication was diagnosed as managing antibiotic therapy, which bacteriological monitoring is to be implemented?

Statement A: In relation to the treatment in progress the aim is to implement the empirical coverage of likely pathogens and gram negative multiresistant (GoR C), while the use of antifungal is indicated only in case of their isolation (GoR B).

Statement B: Cultures in patients at risk of nosocomial infections should always be performed on:

- intra-abdominal material during surgery or percutaneous drainage,
- blood in case of fever over 38°C or after invasive device removal (GoR C).

The presence of postoperative septic complications requires a consultation by infectiologist.

4. What kind of monitoring and what complementary therapy should be implemented in the presence of septic complication?

Statement A: The level of monitoring should be evaluated according to the NEWS system (14).

Statement B: The volume of perioperative fluids must be managed according to the criteria of the "goal directed therapy" (15).

Statement C: Nutritional support should be appropriate starting with early enteral therapy, according to the specific clinical condition.

5. What therapeutic approach per the diagnosed medical case should be chosen:

5.1. What factors influence the therapeutic approach?

Statement: the clinical approach is recommended as a function of the following factors:

- patient at high risk per ASA and P-POSSUM scores;
- systemic conditions for progressive clinical deterioration or worsening of sepsis and MODS indicators (SOFA Score);
- presence of signs of abdominal guarding;
- location and grading of anastomotic leakage;
- presence and localization of abscess collections.

5.2. When do we implement the interventional treatment, or limit the treatment to only drainage of previously placed?

Statement: The conservative management can be seen as a choice only in the presence of intra-abdominal abscesses localized and/or low flow localized dehiscence, drained, without abdominal guarding either signs of systemic involvement (16) (GoR C).

5.3. What indications recommend a surgical approach?

Statement: It is recommended a surgical approach to:

- an ostomy must be created in the presence of anastomotic dehiscence;
- the prompt treatment of the primary foci in the presence of sepsis with clinical deterioration and/or signs of abdominal guarding.

Type of surgical approach: this consensus does not provide any evaluation about the technique (open or laparoscopic) to perform an ostomy or a direct approach to the abdominal septic source.

5.4. Which surgical approach can be implemented in the presence of gastroduodenal dehiscence?

Statement A: Dehiscence of gastroduodenal suture requires surgery in the presence of an uncontrolled fistula (GoR C).

5.5. Which surgical approach can be implemented in the presence of intestinal or ileum - colic dehiscence?

Statement A: Ileal or ileo-colonic anastomotic leakage should be treated with resection and primary anastomosis according to clinical judgement (GoR C).

To be evaluated: in case of a second dehiscence according to the clinical condition and the grade of disease consider to implement damage control strategy.

5.6. Which surgical approach can be implemented in the presence of colonic or colorectal leakage?

Statement A: The anastomotic leakage with systemic and/or peritoneal involvement require early execution of Hartmann' procedure with cleaning and drainage of septic focus (GoR C).

Statement B: The anastomotic leakage can be treated with stomy and drainage if it is a extraperitoneal leak or grade A and B of fistula (GoR C) (7).

6. When it may be necessary to use the technique of open abdomen?

Statement A: Damage Control strategy can be recommended in a high-risk patient with not complete peritoneal cleaning, visceral hypo perfusion, inability to perform an ostomy and/or tertiary peritonitis (GoR C).

To be evaluated: the opportunity of choosing a damage control strategy with an open abdomen to facilitate early recanalization.

Open abdomen management: This consensus has not developed any guidelines for the management of the open abdomen for abdominal sepsis, and postpone this issue topic to a subsequent evaluation, inside the SICUT, about these main topics: criteria, perioperative management, implementing approach, risk of complications and closing techniques.

DISCUSSION

This study, aiming presenting a consensus agreement regarding the management of septic complications following emergency abdominal surgery, was carried out by an Italian group of experts with a very rich experience in the field of emergency surgery, appointed by SICUT.

SICUT is the most powerful and best organized European scientific society in the field of emergency surgery. It has collaboration link with the International Society of Emergency Surgery and with other similar European societies, including the Romanian Society of Emergency and Trauma Surgery, which is concretely helped by taking part in conferences of emergency surgery organized in Bucharest, Sinaia and Iasi. SICUT, a model scientific society has expertise in the management of emergency surgery, including postgraduate learning in the field. SICUT, the oldest society of this kind in Europe and a model to be followed, has expertise in the management of emergency surgery, including postgraduate learning in the field. SICUT has a rich tradition in implementing consensus, studies and guides for good practice. During the presidency of Prof. Franco Stagnitti three consensus studies have been reached at. They have been promoted by national emergency conferences in Italy and a successful postgraduate live course at Matelica, in December 2016.

A consensus was preached often average a period of six months and 45 experts and 37 experienced surgical centers, including university were included. The consensus under discussion was presented and debated at the National Congress of Surgery from Rome in September 2016. After the definition of secondary and tertiary peritonitis, of postoperative abscess and anastomotic leaks the study group reached a powerful consensus of the clinical, biologic and imagistic diagnosis of septic complications in emergency surgery and multidisciplinary complex treatment of these complications. The only method of reducing the morbidity rate is to follow the septic complications of postoperative surgery, including the early diagnosis and the individual treatment following precise criteria.

After defining secondary and tertiary peritonitis, postoperative abscesses and anastomotic fistulae, the study group reached a strong consensus regarding clinical s, biological and imaging diagnostic of septic complications after emergency surgery and a complex multidisciplinary treat-

ment. Careful monitoring of postoperative evolution of emergency surgery, an early diagnosis and individualized treatment of postoperative complications, using precise criteria are the only method that can reduce mortality. An unfavorable evolution on the third postoperative day, accompanied by fever and abdominal signs, ineffective abdominal drainage, leukocytosis, increased PCR and procalcitonin require an early diagnosis, both imagistic (ultrasound, CT with contrast material) and bacteriological (culture of secretion drained, blood cultures). Decision criteria in choosing a complex multidisciplinary treatment are include: the clinical risk assessed by ASA, P-Possum, deterioration of general condition (New Sepsis Score, MODS-SOFA), peritoneal signs, presence of anastomotic dehiscence, characteristic of abdominal sepsis.

Treatment begins with broad-spectrum antibiotics (attention being paid to nosocomial infections; antifungal therapy is indicated only in the presence of fungi). If no general signs are present, anastomotic leek points to type A and the abscess is drained, while antibiotics continuing to control drainage. In case the peritoneal cavity is not drained, abscess is multiple and therefore interventional radiology is recommended. In the presence of systemic signs, dehiscence is of type B and the abscess is drained, is recommended a stoma. In the presence of systemic signs, the dehiscence is of type C and the identification of peritoneal signs require iterative lavage and peritoneal drainage. In case of uncontrolled gastro-duodenal fistula or in the case of ileo-colic leek, resection and anastomosis are recommended (in the case of iterative fistula, damage control strategy is to be followed). Hartmann operation is the solution in the case of colon - rectal fistula.

CONCLUSIONS

This paper reports the consensus agreement of a panel of Italian surgical experts - on the behalf of SICUT - covering early recognition and management of septic complications after emergency surgical procedures.

It is important to remark that although this consensus is in line with current international strategies and previous published guidelines, this study summarizes the agreement reached at by a panel of experts and further developed by adhering to common clinical practices and by using a well-defined methodology. Ongoing studies aim at identifying criteria for establishing a damage control in the case of open abdomen to facilitate early recanalization.

STRUCTURE-BASED DESIGN, SYNTHESIS AND ANTITUMORAL EVALUATION OF ENULOSIDES

The purpose of this research is to designe and obtaine in high yields a new class of antitumoral agents with lower structural complexity. The general strategy for the synthesis of enulosides is based on the use of glycals as starting materials. From the pharmacological point of view, some synthetic enulosides exhibited activity against Mycobacterium tuberculosis H37Rv and they can also act as glycosidase inhibitors. All compounds exhibited high antitumoral activity in micromolar range against the tested tumor cell lines. (Santos JAM, Santos CS, Almeida CLA, et al. Structure-based design, synthesis and antitumoral evaluation of enulosides. *European Journal of Medicinal Chemistry* 2017, 128: 192-201).

ADENOSIN TRIPHOSPHAT BIOLUMINISCENCE IN HOSPITAL CLEANING-A METHOD TO INFLUENCE INVASIVE FUNGAL INFECTIONS (Abstract). Invasive fungal infections are infections determinate by fungal invasion and can be endogenous from patient mycobiome or through horizontal transmission from medical workers' hands and from patients hospital environment especially candidemia with *C. parapsilosis*. Candidemia is one of leading bloodstream infections associated with healthcare situated on fourth position and USA with high mortality rates especially for immunosuppressed patients. Demonstrating the level of cleaning using adenosine triphosphate bioluminescence technique we can improve the cleaning and hand hygiene and can influence decreasing of invasive fungal infections transmitted by hands. **Material and methods:** We have evaluated 200 samples from hands and patient environment on 2 hospitals with pneumology and infectious diseases profile (I and II) using bioluminescence to establish the status of hygiene and to determine measures of cleaning. **Results:** Regarding hand hygiene the level of relative light units over the values recommended by producer (FAIL) was 66% (6 of 9) in unit I and 75% in unit II (3 from 4). Regarding the level of cleaning in other places in direct contact with patients like toilets, bed bar, commodes the results were FAIL over 60%. **Conclusions:** In this moment in hospitals the hygiene is evaluated visually and no objective method was implemented beside the sanitation tests in Romania. ATP Bioluminescence evaluates in 15 seconds the level of cleaning in comparison with other methods and generates input in cleaning process, influencing indirectly decreasing hospital acquired infections including invasive fungal infections, together with other measures like education, antibiotic stewardship, increasing patient safety. In hospitals evaluated cleaning of hands and surfaces need improvement and investment in cleaning products and processes monitoring.
Keywords: ATP BIOLUMINISCENCE, INVASIVE FUNGAL INFECTIONS, HAND HYGIENE, CANDIDA PARAPSILOSIS, PATIENT SAFETY.

Invasive fungal infections (IFI) are the effect of the advances in healthcare. Candidemia is on the top level of healthcare associated infections being in fourth place in hospital acquired infections. Five species are the most species found responsible of 92% of the candidemias *C. albicans*, *C. glabrata*, *C. parapsilosis*, *C. tropicalis*, *C. krusei* (1). There are multiple factors which can determine invasive fungal infections

(risk factors) like immunosuppression, prolonged antibiotic use, totally parenteral nutrition, corticotherapy, chemotherapy and immunosuppressive therapy post-transplant, invasive devices. *C. parapsilosis* is associated more with hand hygiene and especially on extreme ages, elderly and neonates. Bioluminescence is a special method which measures the level of adenozintriphosphate (ATP) on surfaces after interacting with an enzyme named luciferases. The method was used in food industry where the security of hands and environment are on high level. ATP is present in fungal cells, bacteria and other organic compounds. Identifying ATP we receive indirectly data about fungal charge in hands and surfaces. ATP is an organic molecule as a source of energy. Animals, plants, bacteria, yeast and molds are producing and destroying ATP for biological processes. ATP is the premium molecule for energy transfer inside the cytoplasm. ATP identified on a surface indicates that this surface is not clean and can support the growing of fungal and bacterial colonies. Researchers from Brasil have compared the genotype of *C. parapsilosis* of patients in an outbreak and they identify the same species on patients with healthcare workers (2) and using bioluminiscence ATP hygiene monitoring and improving cleaning in United Kingdom the researchers decrease hospital acquired infections (HAI) with *Staphilococcus aureus and Clostridium difficile* (3, 4). Our epidemiology data between 2010-2016 show an 10.6% involvement of *C. parapsilosis* in invasive fungal infections (IFI) in INBI Matei Bals Bucharest (5). We can estimate that monitoring ATP we can have a clear image about the cleaning of one surface or hands or instruments and improving cleaning of hands and patient in hospitals we influence directly decreasing of *C. parapsilosis*, increasing the patient safety.

MATERIAL AND METHODS

We are using one device called luminometer called System Sure Plus (trademark of Hygiena company) (6) and a swab (Ultrasnap) for collection the probe on 10 cm^2 for gathering organic material from healthcare workers and patient environment (bed, commode, toilet, spaces in the hospital) in two units on different wards in infectious diseases and pneumology. The swab has on top one reserve with luciferases enzyme which we will open after we swab the surface and close it to interact enzyme with organic material from swab. Enzyme with organic material generates light and we immediately measure this value with one luminometer (fig.1) which counts *Relative Light Units* (RLU).

The more RLU we have the more contaminated is the surface. Proving, we can take immediately actions in cleaning. Hand hygiene is hard to implement in hospitals and the most resistant are doctors with 30% compliance even hand hygiene can decrease with 20-50% hospital acquired infections (7).

We have evaluated 200 swabs from 2 hospital units I and II (100 swabs for each hospital) from different areas–hands of healthcare workers and different surfaces. We have compared the values with the recommendation of producers for different areas for PASS/FAIL result to evaluate the level of contamination (tab. I).

For hand hygiene 60 RLU was the limit for a clean hand recommended by producer of a device to qualify as a clean hand. Centers for Diseases Control and Prevention (CDC) started one campaign “Clean hands,

Save Lives" (8) to create awareness about the capital importance of hand hygiene. 1 of 25 patients acquired at least one healthcare associated infection at any given day.

TABLE I
Values of RLU recommended for PASS/FAIL result

Applying places	Limits	
	PASS (RLU)	FAIL(RLU)
Public places in hospital	< 150	> 300
Sterilization	< 10	> 20
Washing disinfectors	< 5	> 10
Meal preparation	< 10	> 30

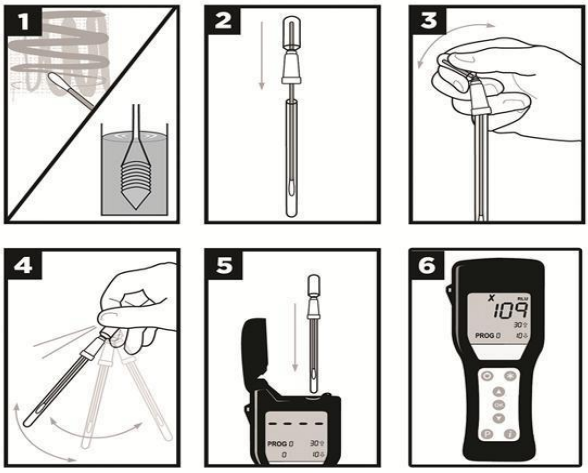

Fig. 1. Luminometer swab and measure steps
(System Sure Plus manual - Hygiena LLC (6)

Hand hygiene should be one part of a multimodal promotion strategy and strong measures and studies showed increasing of compliance significantly among nurses and nursing assistants, but remained poor among doctors in a study done by Pittet et al.(9). Healthcare associated infections decreased (prevalence of 16.9% in 1994 to 9.9% in 1998), MRSA transmission rates decreased (2.16 to 0.93 episodes per 10,000 patient-days;), and the consumption of alcohol-based hand rub solution increased from 3.5 to 15.4 L per 1000 patient-days between 1993 and 1998 (9).

Even education and questionnaires and conferences rises the compliance, nothing is more clear that showing to somebody in a few seconds about the level of his hands following by wash and show again. We say that bioluminescence is similar with speed radar for detecting and transform behavior and self-consciousness.

RESULTS

If 60 RLU is the value recommended by manufacturer we can notice that 6 from 9

results (66%) are FAIL ranking and 3 from 9 (33%) are PASS. We can conclude that most of the hands are dirty at one moment of the day (10.00) (tab. II).

Regarding the toilet of patients 2 swabs from 7 (28.57%) were considered PASS and the rest FAIL (71.43%) (tab. III).

In the second hospital 25% of swabs are PASS, 75 % were FAIL and the same result was on patient toilet. Regarding patient environment, we have taken swabs from patient bed bar and commode and we had the following results: 3 /6 (50%) samples are PASS regarding bed bar and 5/6 (83%) samples are PASS for commode (tab. IV, V).

TABLE II

4	92	560

One sample from 4 (25%) were PASS and 3 from 4 were FAIL regarding bed bar and the same values for commodes.

DISCUSSION

There is no consensus about monitoring of cleaning and in our country: visual inspection, Aerobic Colony Counts (ACC) is used and ATP. The literature has shown that inadequate cleaning identified by visual inspection, ACC, and ATP was 11.8%, 20.0%, and 50.6% before cleaning and 4.7%, 5.9%, 21.2% after cleaning (10).

From our study, we have demonstrated difference between visual inspection and ATP monitoring, after cleaning process, obtaining on hand hygiene failure on 66% (6 of 9) in unit I and 75% in unit II (3 from 4). Regarding the level of cleaning in other places in direct contact with patients (toilets, bed bar, commodes) the results were failed over 60%. In the meta-analysis of Almodio et al., the percentage of surfaces exceeding the chosen cut-off limit showed a failure rate varying from 21.2% to 93.1% before cleaning and from 5.3% to 96.5% after cleaning. The benchmarks were between 0-500 RLU (11).

This method has opponents because is not a direct identification of germs. The method is an indirect estimate of presence of ATP from fungal cells, but also bacterial cells and other cells alive and the low demands identification of germs. Because this identification in the microbiology laboratory needs 24-48-72 hours this method can give us an immediately orientation and can guide the swabs orientation used in microbiology.

Taking in consideration that candidemia is the fourth place in bloodstream infections, and *C. parapsilosis* was identified on the staff hands, implementing this technology in monitoring the hand hygiene and patient environment will decrease the level of these infections and all healthcare associated infections.

CONCLUSIONS

Our study analyzed the level of cleaning on hands and patient environment and values showed failure in most of the swabs. We estimate that determining cleaning using ATP followed by cleaning processes can decrease of invasive fungal infections. These results create us the input to propose to the Ministry of Health a project for all the emergency hospitals and control departments to have this technology implemented as the “radar” of cleaning.

COFFEE INTAKE DECREASE THE MULTIPLE SCLEROSIS RISK

Health benefits and health risks of coffee drinking were evaluated by numerous studies that used human or animal models. Some studies have linked coffee consumption with neuroprotective effects by decreasing inflammation and demyelination. The influence of coffee consumption on the risk of multiple sclerosis (MS) has been investigated in two retrospective case–control studies conducted in Sweden and the US. Both trials included people aged over 15 years who were diagnosed with MS and have investigated consumption habits of caffeinated coffee in different periods of age. The two studies have involved a total of 2779 cases and 3960 controls. The risk of MS among participants which consumes coffee was compared with the risk of MS among participants who never drank coffee, by calculating ORs with 95% CIs. The results showed a reduced risk of MS among those who reported a consumption of coffee exceeding 6 cups daily (OR 0.70 in the Swedish study, and OR 0.69 in the US study) in comparison with participants who never drank coffee. Additional studies are needed to determine which of biologically active constituents of coffee determines these results, to use them in multiple sclerosis therapy (A K Hedström; E M Mowry; M A Gianfrancesco; X Shao; C A Schaefer; L Shen; T Olsson; L F Barcellos; L Alfredsson. High consumption of coffee is associated with decreased multiple sclerosis risk; results from two independent studies. *Neurol Neurosurg Psychiatry* 2016; 87: 454-460).

SURGICAL MANAGEMENT OF TYPE A ACUTE AORTIC DISSECTION IN PATIENTS WITH MARFAN SYNDROME: A SINGLE CENTER EXPERIENCE (**Abstract)** Introduction Acute aortic dissection is the most common cause of death in patients with Marfan syndrome and untreated aortic root enlargement. Emergency surgery for replacement of the ascending aorta has the potential of life saving procedure, but is associated with high morbidity and mortality. Long-term outcomes after surgical repair of acute aortic dissection type A in patients with Marfan syndrome are limited. **Material and methods**: We made a retrospective study concerning emergency surgical intervention for acute aortic dissection type A, by Bentall procedure, performed in Emergency Institute for Cardiovascular Diseases „Prof dr. C. C. Iliescu" Bucharest between January 2005 and July 2014. We included 332 patients with type a acute aortic dissection divided into two groups: group A - 16 patients with Marfan syndrome and group B - 316 patients with other etiologies. We analyzed differences between these two groups regarding perioperative characteristics, surgical technique and short and long-term morbidity and mortality. **Results**: The patients from group A were significantly younger than those in group B (35.1±12.7 years *vs.* 56.8±7.1 years; $p<0.001$). Arterial hypertension was three times more common in group B as compared to group A ($p<0.001$). The incidence of postoperative morbidity, and intraoperative and 30-days mortality death rates were similar between groups, but overall mortality at 10 years was lower in group A (31.3%) *vs.* group B (44.9 %). **Conclusions**: Emergency surgical in Marfan syndrome, by Bentall procedure could improve perioperative morbidity and mortality of patients with acute aortic dissection, but need an early diagnosis, proper medical therapy and imagistic surveillance. **Keywords**: MARFAN SYNDROME, TYPE A ACUTE AORTIC DISSECTION, BENTALL PROCEDURE.

The aortic disease is a severe disorder with bad prognosis. This term encompasses a lot of different of conditions like aneurysm, dissection, atherosclerosis and a general stiffening of elasticity associated with ageing. The etiology is complex and include injury, arterial hypertension, bicuspid aortic valve or genetic disorders like Marfan syn-

drome (MS), Ehler–Danlos syndrome, osteogenesis imperfecta, or Turner syndrome. The aorta has a high degree of elasticity, necessary for the propulsion of blood in the systemic circulation. This feature is allowed by connective fibers, where the major components are elastin and collagen. Any alteration of quantity and/or architecture of these fibers induces mechanical changes that generate aortic disease.

The Marfan syndrome is a disease of connective tissue. It presents an autosomal dominant inheritance and affects 1/5,000 individuals. The majority of cases presents a *FBN1* gene mutation. Other mutations (around 10% of cases) concern *TGFbR1/2, COL3A1* or *ACTA2* genes. The diagnostic evaluation for MS is difficult due to the phenotypic variability, different age depending manifestations, the absence of well-established criteria, and a difficult differential diagnosis. The diagnostic criteria improve the clinical early diagnosis, but accuracy is also important to diminish the deleterious and irreversible consequences of diagnosis errors. The main clinical signs interest ocular, cardiovascular and skeletal systems, but also could be discovered changes in skin, lung or dura. The diagnosis of MS is based on so called Ghent criteria, established in 1991. The revisited Ghent criteria help the clinician in diagnosis of MS. Thus, when is identified a single case in a family, the diagnosis of MS could be established if is present one of the following associations: dilatation of aortic root (Z=2) and *ectopia lens*; dilatation of aortic root (Z=2) and *FBN1* gene mutation; dilatation of aortic root (Z=2) and a clinical score more than 7 or *ectopia lens* and pathogenic *FBN1* gene mutation for dilatation of aortic root. Where the diseases are present in other members of the same family, the diagnosis of MS is sustained by the association between familial history of MS and *ectopia lens*, dilatation of aortic root (Z=2) or clinical score more than 7. Excepting the dilatation of aortic root and *ectopia lens* the clinical score contains elements of skeletal, cardiovascular, ocular or skin. The main component of clinical score are: wrist and thumb sign, *pectus carinatum*, hindfoot deformity, pneumothorax, dural ectasia, and *protrusio acetabuli*.

The *FBN1* gene is located 15q21 and comprises 65 coding and 3 alternatively spliced exons. It encodes a glycoprotein - fibrillin-1 - with a molecular weight of 350 kD. Fibrillin-1 is a major component of the extracellular micro fibrils, which are connected to extracellular matrix to form sheaths around elastic fibers (Bonetti, 2009). Fibrillin-1 present three types of domains: an epidermal growth factor (EGF) like motif (many of these have a highly conserved calcium-binding sequence (cbEGF)), a latent transforming growth factor beta (TGF-β) binding protein motif and a fusion module. The main type of mutation (>2/3) is a missense mutation that affects the cbEGF modules, but also were described frameshift, splice site and nonsense mutations [Turner et al., 2009]. Except the mutations that concern exons 24–32 usually associated with a severe phenotype (“neonatal Marfan syndrome”) it is impossible to establish a genotype-phenotype correlation in MS.

The major cause of death in MS is acute aortic dissection (1). Without surgical treatment, this condition leads to death in more than 95% cases. Despite advances in surgical technique, the early mortality remains high. Treatment of patients with type A acute aortic dissection and Marfan syndrome is an emergency lifesaving proce-

dure (2). In a type A aortic dissection, simple replacement of ascending aorta is usually the best option, but when Marfan syndrome is the underlying cause of dissection, this option is not feasible because of important aortic root dilatation (3, 4). Under these circumstances, replacement of the ascending aorta and the entire aortic root represents the adequate surgical treatment (5). This study aimed to identify differences between perioperative characteristics, surgical technique and early and late mortality and morbidity in a group of patients operated for acute aortic dissection with and without Marfan syndrome.

MATERIAL AND METHODS

Patients cohorts

We made a retrospective study on a cohort of 332 patients underwent an emergency surgical intervention for acute aortic dissection type A. This surgical procedure was applied in Emergency Institute for Cardiovascular Diseases "Prof dr. C. C. Iliescu" from Bucharest, between January 2005 and July 2014. We excluded all patients with type B acute aortic dissection and those with type A acute aortic dissection complicated with mesenteric ischemia. The 332 patients were divided into two groups: group A including 16 patients with Marfan syndrome and Group B including the remaining 316 patients with acute aortic dissection by other etiology. We analyzed demographic data and perioperative features of the patients from available patients' medical records. Information regarding long-term survival was obtained from the National Institute of Statistics/The Register of Persons Records.

Surgery procedures All patients were evaluated before surgery by transthoracic and transesophageal echocardiography, in order to identify the location of intimal tears and the extension of the dissection.

The surgical strategy implied resection and replacement of the dilated segment (aortic root, ascending aorta or aortic arch) with a prosthetic graft, and exclusion of access intimal tear. Surgery was performed via standard median sternotomy with total cardiopulmonary bypass (CBP). Depending of the integrity of the peripheral vessels, cannulation is initiated via right axillary artery or right femoral artery for arterial access and right atrium for venous return. A vent was placed in the left ventricle via the right superior pulmonary vein. Myocardial protection with cold blood cardioplegia was initiated through retrograde route after cross clamping the ascending aorta. Completion of cardioplegia is achieved after transverse aortotomy at the level of ascending aorta and administration of the remaining dose of cold blood cardioplegia via direct cannulation of both coronary ostia. Inspection of the ascending aorta and the aortic valve was performed, together with the resection of the segment including the proximal entry tear, followed by repair or replacement of the aortic valve, as needed. After reaching a mean temperature of 25-28°C, during circulatory arrest the aortic clamp was removed and the entire aortic arch was examined and replaced whenever an aortic arch tear has been identified. The distal anastomosis with prosthetic collagen impregnated low porosity graft was then completed under circulatory arrest with anterograde selective cerebral perfusion. Teflon strips and sometimes biological glue were used to reinforce the distal suture lines. After completion of the distal anastomosis, the prosthetic graft and the great vessels are de-aired, and extracorporeal circulation is restarted after a cross clamp is placed on the prosthetic graft. Finally, in

the supracommissural aortic repair the proximal anastomosis is performed in a similar fashion using Teflon strips and biological glue. In the Bentall procedure we use a premanufactured conduit with Valsalva sinuses and a mechanical valve, each coronary button was sutured with Prolene 6.0 to the Valsalva part of the premanufactured conduit. Eight surgeons performed the operations throughout this period, using a similar perioperative and surgical strategy according to current available guidelines and hospital`s established protocols.

Bentall procedure

As the abnormalities found in patients with Marfan syndrome often compel to replacement of the ascending aorta and the aortic valve with a composite prosthesis containing a mechanical or bio prosthetic cardiac valve enclosed in a tubular polyester graft, operation referred to as the Bentall procedure. The patient is placed on cardiopulmonary bypass using a single venous two-stage cannula, with the arterial cannula in the femoral artery. The ascending aorta is clamped, retrograde cardioplegic solution is administered in the coronary sinus and a vent catheter is placed through the right superior pulmonary vein to the left atrium and left ventricle. The ascending aorta aneurysm is opened via a vertical incision. Traction stitches are placed above each aortic valve commissure to expose the aortic root and the aortic valve is excised. The coronary arteries are mobilized with buttons of sinus aorta and the remaining sinus aorta is removed. After calibration of aortic annulus, the composite prosthesis is sewn to the aortic annulus using mattress stitches of 2-0 braided polyester with PTFE felt pledges, starting from the right coronary sinus. Reimplantation of the coronary arteries requires direct anastomosis of the coronary ostia to the graft, but it can also involve a bypass graft or a polyester extension depending on the position of the ostia in relation to the aneurysm or dissection. The right coronary anastomosis is performed after completing the left coronary anastomosis, with deep bites into the aorta using continuous stitches of 6-0. The distal end of the graft is then shortened to allow a direct end-to-end anastomosis.

Statistical methods

Continuous variables are presented as mean ± standard deviation and compared using the Student t-test. Discrete variables were expressed as counts and percentages and comparisons between groups were done with the χ^2 or Fisher`s exact test, when appropriate. Five-year survival rates were estimated using Kaplan-Meier analysis and comparisons between groups were performed with the log-rank test. A two-sided P-value of 0.05 was considered significant for all tests. All analyses were conducted using *SPSS 21.0* (*SPSS*, Inc., Chicago, IL, USA).

RESULTS

Preoperative data are presented in Table 1. Only two statistical significant differences were discovered: patients with Marfan syndrome were significantly younger than patients of group B (35.1±12.7 *vs.* 56.8±7.1 years; $p<0.001$) and arterial hypertension was more common among patients' form group B (79.7% in group B *vs.* 25% in group A; $p<0.001$).

The operative data are reported in Table 2. These data showed only two significant differences. In Marfan syndrome group the replacement of aortic root and first portion of ascending aorta was more frequent applied (81.3% *vs.* 33.2%, $p<0.001$). Similar

value concerned the replacement of aortic root and entire ascending aorta more frequent applied in Marfan syndrome (56.3% *vs.* 18.4%, p=0.001).

TABLE I

Preoperative characteristics

Preop. characteristics	Group A (n=16)	Group B (n=316)	p value
Gender (female)	37.5% (6)	39.9% (126)	0.85
Age (years)	35.1±12.7	56.8±7.1	<0.001
Arterial hypertension	25% (4)	79.7% (252)	<0.001
Diabetes mellitus	0% (0)	5.7% (18)	1.00
Renal impairment	18.8% (3)	45.9% (145)	0.033

TABLE II

Operative data

Intraoperative characteristics	Group A (n=16)	Group B (n=316)	p value
Arterial cannulation sites			
Axillary artery	56.3% (9)	69.0% (218)	0.29
Ascending Aorta	12.5% (2)	2.5% (8)	0.08
Femoral artery	25.0% (4)	22.5% (71)	0.76
Axillary and Femoral artery	0.0% (0)	2.2% (7)	1.00
CPB time (min)	253.3±81.1	247.0±113.2	0.80
Cross clamp (time)	168.0±54.8	144.8±71.9	0.18
Cerebral perfusion (%)	33.3 % (5)	43.1% (129)	0.45
Circulatory arrest (min)	20.3±26.0	24.3±32.5	0.70
Temperature Circulatory arrest (ºC)	24.4±5.4	24.0±4.1	0.81
Aortic segment replaced			
Aortic root and first portion of ascending aorta	81.3% (13)	33.2% (105)	<0.001
Ascending aorta	6.3% (1)	30.7% (97)	0.046
Aortic root and entire ascending aorta	56.3% (9)	18.4% (58)	0.001

*CPB – cardio-pulmonary bypass.

All patients with Marfan syndrome had aortic insufficiency at the time of diagnosis, and the majority of them had grade 4 aortic regurgitation (11/16 patients). The Bentall modified operation (BMO) was performed in 11 patients, while in the rest cases were applied other type of surgical interventions.

Postoperative characteristics were evaluated but we did not found any significant differences between groups concerning mechanical ventilation time (106.6±252.5 hours in group A *vs.* 211.4±397 hours in group B, p=0.15) or length of stay in the intensive care unit (8.9±15.6 days in group A as compared to 13.8±19.5 in group B; p=0.25).

Follow-up was 100% complete as data were received from the National Institute of Statistics / the Register of Persons Rec-

ords. The mean follow-up of the study was 4 years (standard error ±2.76 years, min 1 day, max 10.2 years, and median 3.8 years) with x patients at the end of the study. Intraoperative death rate was similar in both groups without statistical significance (12.5% in group A *vs.* 6.0% in group B; p=0.27). The incidence of postoperative morbidity was not significantly different between the two groups, with the main incidents being: stroke, mediastinitis, and multisystem organ failure in both group. The only major difference was the acute kidney disease present in only 18.8% patients from Marfan syndrome group compared with 58.2% in group B (p=0.002). Also, we not found statistical significance differences regarding 30-day mortality (18.3% in group A compared with 30.1% in group B; p=0.41). Similar results we found the one-year mortality (7.7% in group A *vs.* 9.2 % in group B; p= 0.87) and mortality at 10 years (31.3% in group A *vs.* 44.9 % in group B; p= 0.28).

DISCUSSION

Marfan is a systemic connective-tissue, autosomal-dominant inherited disorder characterized by mutations in the fibrillin-1 gene (FBN1), with a prevalence of approximately 1 in 5000 individuals (6). There is no sex, racial, or ethnic predilection, and one third of cases present without previous family history (7). Management of Marfan syndrome with cardiac symptoms includes medical treatment with beta blockers and regular screening to assess the progression of the aorta dilatation to a significant diameter aneurysm, when surgical treatment is required to prevent to prevent dissection or rupture (8). Abnormalities frequently found in patients with Marfan syndrome include aortic root dilatation, associating aortic insufficiency due to aortic annulus dilation or bicuspid aortic valve.

Replacement with a composite graft containing a mechanical valve and a polyester tube graft - the modified Bentall operation - is the gold standard for such patients with corresponding aortic valve cusps pathology (9-11). For young patients with isolated aortic insufficiency with pliable aortic valve cusps, however, valve sparing root replacement might be a good option in experienced institutions (12). Yacoub and colleagues in 1983 introduced the aortic valve remodeling technique with replacement of the ascending aorta and the sinuses of Valsalva (13). David described replacement of the aorta with native aortic reimplantation into a prosthetic tube graft (12). For the past several years, the David aortic valve reimplantation operation has been the procedure of choice for patients with aortic root enlargement and pliable aortic valve cusps (14). Patients with severe damaged cusps are not good candidates for valve sparing operations (15).

Surgery for acute type A aortic dissection remains associated with high operative mortality and morbidity, and adding a long and complex aortic valve sparing may not be the safest approach (10). Current ESC/EACTS guidelines for the management of valvular heart disease state that, surgery should be considered in patients with Marfan syndrome with risk factors (family history of dissection, size increase 2 mm/year in repeated examinations) or who have aortic root disease with a maximum ascending aortic diameter of ≥45 mm (Class II a, Level C evidence) (16).

In a study analyzing the impact of surgical intervention in patients with Marfan syndrome, Ohsubo et al. showed that valve preserving aortic root reconstruction result-

ed in improved postoperative quality of life compared with Bentall operation, by reducing late complications related to anticoagulants (17). Unfortunately, in patients presenting in the acute setting of aortic dissection, valve-sparing root replacement or reconstruction is often not possible. After initial repair of an ascending aortic aneurysm, a significant number of patients have subsequent surgeries at other sites throughout the aorta, indicating that Marfan syndrome is a disease involving the entire aorta. Some studies show that patients with Marfan syndrome who had a dissection at the time of the first aortic surgery were more likely to require subsequent aortic surgery than those who underwent prophylactic composite graft repair of an aortic aneurysm (18).

As with any reconstructive procedure, these operations must be performed with intraoperative echocardiography to assess valve morphology and function at the end of the procedure. Restoration of normal aortic cusp geometry is the single most important technical aspect of aortic valve–sparing operations. In addition, to have a competent valve with no or only a minimal central AI at the end of the procedure, no cusp should be prolapsing, and the coaptation height has to be well above the level of the nadir of the aortic annulus.

Finally, patient selection also is important. Patients with severe AI before surgery often have damaged cusps and are not good candidates for this operation. Most of our patients had normal or near-normal cusps on.

Study limitations

This study has several limitations, especially related to the retrospective design of the study and the small number of patients in group A. Under these circumstances, advanced analysis, such as multivariable analysis, is unreliable. Nevertheless, our study provides meaningful information on management of patients with Marfan syndrome presenting with acute aortic dissection.

CONCLUSIONS

Due to the unstable condition of patients with Marfan syndrome presenting with acute aortic dissection, the Bentall operation was the most common surgical procedure performed in our cardiac surgery hospital. The operative mortality was relatively high, but not different in comparison with group without Marfan syndrome. The long-term survival of the patients with type A acute aortic dissection and Marfan syndrome was suboptimal. Early diagnosis and regular CT and EET surveillance of patients with Marfan syndrome and a proper medical therapy could reduce the incidence of the aortic dissection or aortic rupture, and may improve the results by making elective valve sparing operation feasible.

LEFT ATRIAL, LEFT ATRIAL APPENDAGE AND PULMONARY VEINS ANATOMICAL VARIANTS IN PATIENTS WITH ATRIAL FIBRILLATION VERSUS PATIENTS IN SINUS RHYTHM (Abstract): The aim of the study is to evaluate by multidetector computed tomography (MDCT) the prevalence, location and size of LA (left atrial) diverticula and accessory appendages, the prevalence of PVs anatomical variants and LAA (left atrial appendage) shapes in patients with atrial fibrillation (AF) compared to patients in sinus rhythm (SR). Images obtained by MDCT in a group of 100 patients with <1 year paroxysmal or persistent AF prior to radiofrequency catheter ablation and in a group of 100 patients in SR with unconfirmed or insignificant (<50%) coronary arteries stenoses were compared. The prevalence of LA diverticula (22% in AF group, 19% in SR group) and accessory appendages (6% in AF group, 5% in SR group) was not significantly different between the two groups. Similar sizes of LA diverticula and accessory appendages were registered in patients with AF and in SR. The prevalence of a common left venous trunk was significantly higher in patients with AF (30%) compared to patients in SR (18%) (p=0.047) and proved to be an independent predictor for AF (odds ratio (OR) 1.32; 95% confidence interval (CI) 0.93–1.51; p=0.002) at multivariate logistic regression. LAA had a complex shape but no significant differences concerning the prevalence of the 4 major types were registered between the groups. In conclusion, the only parameter associated with AF was the presence of a left common trunk suggesting that it is either a consequence or a predisposing factor for the development of AF. **Keywords:** ATRIAL FIBRILLATION; SINUS RHYTHM; LEFT ATRIUM; LEFT ATRIAL APPENDAGE; LEFT ATRIAL DIVERTICULUM.

The left atrial appendage (LAA) is a complex morpho-anatomical structure distinct, from an embryological, anatomical and pathophysiological point of view, from the rest of the left atrium.

Atrial fibrillation (AF) is a well-known supraventricular arrhythmia but its exact relation to the LAA shape, left atrium (LA) accessory appendages, LA diverticula and anatomical variants of pulmonary veins (PVs) still remains unclear. In up to 94% of patients with AF, ectopic foci with electrical activity triggering AF have been found in myocardial muscle extensions located at the junction of PVs with the LA (1). Specialized conduction tissue with pacemaker activity

remains at the specified level after the looping process of the heart tube during development (2). Due to its high spatial and temporal resolution, multidetector computed tomography (MDCT) is the non-invasive imaging method of choice for evaluation of PVs and LA prior to radiofrequency catheter ablation (RFCA) in AF. Anatomical variants of LA, LAA shape and PVs with unknown electrical impact are frequently identified when performing cardiac MDCT.

The aims of the current study were to evaluate by means of MDCT the morphology of the LAA; to determine the prevalence, location, and size of LA diverticula and accessory appendages and to analyse PVs anatomical variants in patients with AF compared to patients in sinus rhythm (SR) in order to determine if the incidence of particular aspects of these structures is higher in patients with AF.

MATERIAL AND METHODS

Study design

The current study was designed as a retrospective evaluation carried out in the Radiology Department, Cardiovascular Diseases Institute, Iasi, Romania between September 2012-January 2014. Informed consent prior to examination was obtained in all cases.

Anatomical considerations

LAA is an embryological remnant of the primitive left atrium, morphologically described as a long, narrow, tubular hooked structure situated in the left atrioventricular sulcus close to the proximal part of the left circumflex artery. Posteriorly, it is closely related to the left superior PV, their ostia being separated by a ridge of variable width. This area is travelled by the oblique vein (OV) of the LA that can be sheathed by a myocardial sleeve – a potential electrical communication with the myocardium over the coronary sinus. From a clinical standpoint, LAA develops a distinct pattern of contractions different from the rest of the LA thus explaining its arrhythmogenic role in triggering AF (3) and its association with an increased thromboembolic risk. Wang et al. (4) classified LAA shapes in 4 groups, classification later improved by Kimura et al. (5): "*cactus*": a main lobe of less than 4 cm long, with more than 2 additional lobes; "*cauliflower*": a main lobe of less than 4 cm long, without any forked lobes; "*chicken wing*": a main lobe of more than 4 cm long, with a folded angle of less than 100^0; "*windsock*": a main lobe of more than 4 cm long, with a folded angle of more than 100^0, over 1 cm (fig. 1).

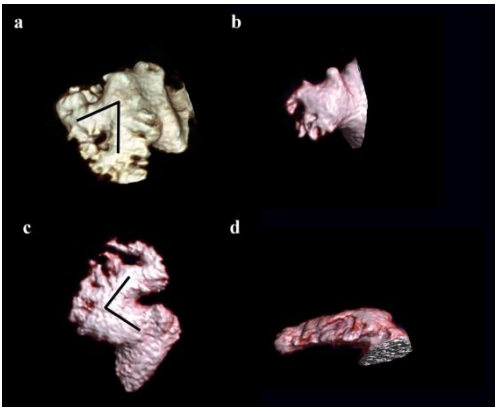

Fig. 1. LAA shapes: (a) "cactus", (b) "cauliflower",(c) "chicken wing", (d) "windsock"

A saccular structure protruding from the LA wall is considered a diverticulum (fig. 2a) if it has smooth walls and a broad-base ostium, or an accessory appendage (fig. 2b) if it has a narrow-base ostium and an irregular inner contour suggesting the presence of pectinate muscles. These saccular structures can occur anywhere on the surface of the LA and are classified according to the involved wall (anterior, posterior, right or left) and their position onto this wall (superior or inferior).

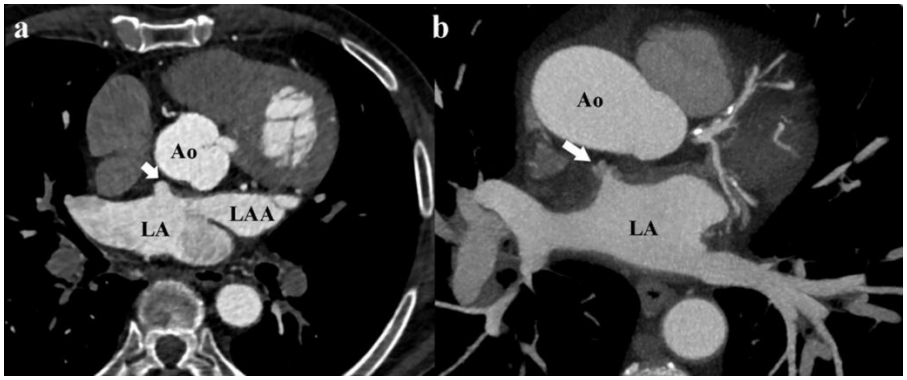

Fig. 2. Appearance of left atrial diverticula (a) and accessory appendage (b) in two different patients

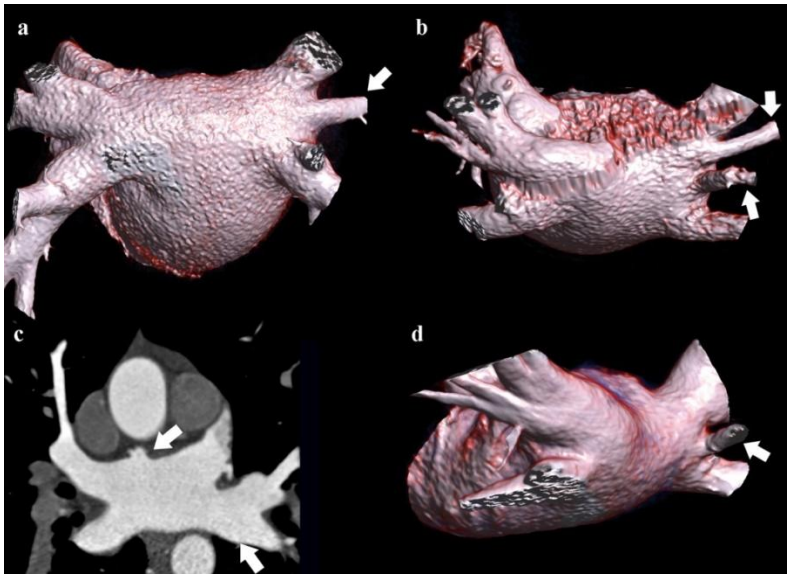

Fig. 3. (a) Separate right middle PV and short common left trunk, (b) Accessory intersegmental PV associated with a right middle PV, (c) long common left trunk and accessory appendage, (d) accessory right intersegmental PV

Most patients present two superior (right and left) and two inferior (right and left) PVs that have a distinct course from that of arteries or bronchi. Normally, the right superior PV drains the right superior and the middle lobes, the left superior PV drains the left superior lobe (culmen and lingula), and the inferior PVs drain the correspondent inferior lobes. Superior PVs ostia are larger than those of the inferior PVs. A minority of cases display variation in number (single antrum for the left/right-sided PVs with a long or short common trunk, supernumerary PVs), size and orientation of PVs. Kato et al. described 6 branching patterns of the PVs: 1) typical

branching pattern (two superior and two inferior PVs), 2) short common left trunk, 3) long common left trunk (fig. 3c), 4) one right middle PV, 5) two right middle PVs, 6) right middle PV and right "upper" PV (fig. 3b) (6). In the current study there were found 2 additional combinations: short or long common left trunk associated with a right middle PV (fig. 3a), and the presence of accessory intersegmental PVs directed towards the apical or a basal segment of the right inferior pulmonary lobe (fig. 3d).

Study groups

The authors retrospectively reviewed a group of 100 patients diagnosed with AF (paroxysmal or persistent) for less than 1 year (63 men and 37 women aged between 23-78 years with a mean age of 56.75 years) and no underlying structural heart disease that underwent cardiac CT examination prior to RFCA and a group of 100 patients in SR (52 men and 48 women aged between 25-79 years with a mean age of 58.74 years) referred for CT evaluation of suspected coronary arteries disease (CAD) but with no or mild (less than 50% diameter stenosis) coronary lesions and no other structural heart disease.

Clinical characteristics of study groups

Patients' clinical characteristics are summarized in Table I. Patients with previous cardiac surgery, other cardiac diseases (except mild CAD) or prior RFCA were excluded from the study.

TABLE I

Clinical characteristics of patients included in the study groups

	AF	SR	p
Number of patients	100	100	-
Age (mean ± SD)	56.75±11.39	58.74±11.23	<0.05
Sex ratio (M/F)	63/37	52/48	<0.05
Body mass index (kg/m^2)	25.6±4	26.1±3.5	n.s.
Diabetes mellitus	4 (4%)	8 (8%)	<0.05
Type of AF	65 paroxysmal, 35 persistent	-	-
Duration of AF (years)	5.2±3.5	-	-

Image acquisition protocol

All 200 patients were examined using a 2nd generation 256-slices dual source MDCT scanner (Siemens Somatom Definition Flash, Siemens Medical Solutions, Germany) with the following scan parameters: 100 or 120 kV tube voltage, tube current modulated by CareDose 4D algorithm (320 mAs reference), 128 x 0.6 mm collimation, gantry rotation time 280 ms. Two imaging protocols were used depending on the heart rhythm and cardiac pathology:

a) High pitch retrospective scanning in patients with high (more than 71 beats per minute) or irregular heart rates in order to perform end-systolic phase reconstructions;

b) High pitch prospective scanning in patients with stable heart rate less than 70 beats per minute.

Metoprololum (Metroprolol LPH 50 mg, LaborMed Pharma S.A., Romania) was administered orally to all patients the morning of the examination if no contraindication was present. Test bolus injection protocol was used for optimal contrast timing. A volume of 20 ml of contrast agent (Iomeron 400, Bracco, Milan, Italy) followed by 25 ml of saline chaser were injected via an 18G cannula placed in the right mediobasilic or mediocephalic vein at

a flow rate of 6ml/sec. A series of dynamic, low-dose monitoring scans were performed (region of interest placed in the ascending aorta) beginning 10 seconds after initiation of contrast agent injection in order to determine the time interval between the start of the test bolus injection and the peak of aortic enhancement. After the aortic peak time evaluation (APT) 2 puffs of nitroglycerin (0.8 mg) were administered sublingually for coronary artery dilation, thus allowing the start of the main examination. An average volume of 85 ml of contrast media and 50 ml of saline chaser were injected and scanning in a single breath hold began after a delay based on the previously determined APT+5 seconds. Optimal reconstructions at different R-R interval percentages were performed (thickness 0.75 mm). Images were reconstructed at 30-80% of the R-R interval in 5% increments and optimal reconstruction interval was chosen for image analysis on a Syngo.via workstation (Siemens Medical Solutions, Germany) by two independent radiologists in order to obtain more objective results.

Statistical analysis

Statistical analysis was carried using IBM SPSS Statistics 22.0 and Excel 15.20 (Mac OS X platform). Quantitative data was tested for normality and presented as mean value ± standard deviation (SD). Student's t test was used to compare means between the AF group and SR group. Qualitative data was presented as percentages and compared using Pearson chi-square test. Multivariate logistic regression analysis was performed to identify independent predictors of AF after adjusting for potential confounders with univariate analysis. A p value of less than 0.05 was considered significant.

RESULTS

AF group

Most of the patients in the AF group had a "*chicken wing*" shaped (43%) or a "*cauliflower*" shaped (25%) LAA. Seven LA accessory appendages were identified in 6 cases, one patient having 2 LA accessory appendages. Six of them were located on the right anterosuperior wall and one on the right anteroinferior wall. Twenty-four diverticula were identified in 22 patients, 2 patients presenting 2 diverticula.

As in the case of LA accessory appendages, most of the diverticula (18 – 75%) were located on the right anterosuperior wall, 4 (16.67%) on the right anteroinferior wall and 2 on the left anteroinferior wall (8.33%). LA accessory appendages had a narrower base (7.42 mm) and were longer (9.38 mm) compared to diverticula (8.8 and 7.1 mm respectively). Considering PVs variants, a common left trunk was the most frequently accounted (30%) followed by separate right middle lobe PV(s) (single or double in 11% of cases). Accessory intersegmental PVs were noted in 6% of cases, while an association of variants was identified in 5% of cases.

SR group

As in AF group, most patients presented a "chicken wing" shaped LAA (55%). Five single accessory appendages and 19 diverticula were found, none of the patients had multiple accessory appendages and in one case 2 diverticula were identified. The most common location for both accessory appendages and diverticula was the right anterosuperior wall, one accessory appendage was located on the left anterosuperior wall and one diverticulum, on the left anteroinferior wall. A common left PVs trunk was identified in 18% of cases, followed by separate right middle lobe PV(s) (12%). An

accessory intersegmental PV was present in 5 cases (5%), and an association of variants in 3 cases (3%). The only parameter the proved to be associated with AF at univariate analysis was the presence of a left common venous trunk (tab. II).

AF – atrial fibrillation; LA – left atrium; LAA – left atrial appendage; PV – pulmonary vein; SR – sinus rhythm

Multivariate logistic regression analysis demonstrated that the only parameter that acted as an independent predictor for AF was the presence of a left common trunk

(odds ratio (OR) 1.32; 95% confidence interval (CI) 0.93–1.51; p=0.002) suggesting that it is either a consequence or a predisposing factor for the development of AF.

DISCUSSION

LA accessory appendages and diverticula are frequently identified in patients undergoing cardiac CT examinations for various reasons, without any association with a congenital pathology. In some cases, it is difficult to differentiate accessory appendages from diverticula as irregularities of the inner wall might be too subtle or the base too wide. Histologically, all cardiac layers form diverticulum's wall, but it can contain less myocardium than normal LA wall thus being translucent. Wan et al. consider that LA diverticula represents an acquired condition secondary to the atrophic thinning of the atrial wall due to various cardiac and systemic pathologies (atherosclerosis, arrhythmias, systemic thrombosis, occlusion of the arteries supplying the atrium, mitral valve disease) (7). Unfortunately, the authors couldn't identify any study published to date to actually certify those findings. Contrary to diverticula, accessory appendages contain pectinate muscles and have contractile properties as it has been demonstrated by Killen et al. Lee et al. that suggested and sustained a common embryonic origin of LA accessory appendages and LAA (8,9).

In the current study groups LA accessory appendages and diverticula were common structures with a cumulated incidence of 28% in the AF group and 24% in the SR group. Diverticula were identified 3.7 more frequent than accessory appendages in the AF group and 4.2 more frequent in the SR group. The prevalence of diverticula in the group with AF (22%) was not significantly higher than in patients without AF (19%) and correlates with previous researches that have stated a prevalence of 23.5 - 36% in patients with AF and 16.7 – 41% in general population or patients in SR (1,7,10-15). Both diverticula and accessory appendages were most frequently located in a right lateral position on the anterosuperior wall. The size of accessory appendages and diverticula was similarly between the two groups and within the wide range reported by other studies (tab. III) (1,7,10-16). Absence of a statistical significant difference in size, location and prevalence of diverticula and accessory appendages between patients in AF and SR pleads against a relation between these structures and the genesis of AF.

Nevertheless, the presence of diverticula and accessory appendages should be signalled to electrophysiologists performing RFCA. Their ostia could be mistaken to those of PVs during procedure, and isolation attempts could determine a perforation of the atrial wall with subsequent hemopericardium. During the current analysis no thrombus was visualized inside these structures.

Anatomical variants of PVs are frequently encountered both in patients with AF and in SR as proved by the results of the current study (prevalence of 52% in AF group and 38% in SR group) and the reviewed literature (tab. III). The predominantly encountered variants were a common left trunk (30% in AF group and 18% in SR group) and 1 or 2 accessory right middle PVs (11% in AF group and 12% in SR group). Our findings are similar to those reported by other authors (6,17-23). A precise knowledge of the anatomy of PVs is mandatory prior to RFCA as non-isolation of a vein could lead to failure of

the procedure, PVs stenosis or recurrence of AF. Cronin et al. state that, given the small diameter of the right middle PV, it is often difficult to identify this vein during procedure, so it might be overlooked (24).

Bittner et al. reported a higher prevalence of a common left trunk in patients with AF as compared with controls. These results were reproduced during our study. We also identified a significant difference between the prevalence of a common left trunk in patients with AF and patients in SR. In order to explain this finding Bittner et al. proposed two hypotheses: 1) congenital variant that constitutes a risk factor for developing AF; 2) acquired condition secondary to the remodelling of LA geometry associated with AF that "pushes" the carina between the two left PVs thus creating a common left trunk (18). In either case, the presence of a common left trunk is associated with the occurrence of AF. Concerning the other PVs variants, prevalence was not significantly different between the two studied groups.

Several authors (tab. III) studied the morphology of LAA in general population, patients with AF and patients with AF and a history of stroke and found it to be complex and heterogeneous (3-5). Di Biase et al. and Kimura et al. proved the existence of a relation between the morphology of LAA and the risk of thrombotic stroke in patients with FA, "chicken wing" shaped LAA being associated with a lower risk of stroke compared to "cauliflower" shaped LAA that was considered an independent predictor of stroke (3,5). In our study group, there was identified no significant statistical difference between the prevalence of different LAA morphologies in patients with FA and patients in SR, thus allowing us to affirm that the shape of the LAA could be of importance only in patients with AF, already at risk for stroke.

AF – atrial fibrillation; GP – general population; SR – sinus rhythm

CONCLUSIONS

LA accessory appendages and diverticula are frequently identified in patients undergoing cardiac CT examinations for various reasons, without any association with congenital pathologies. In the current study groups LA accessory appendages and diverticula were common structures with a cumulated incidence of 28% in the AF group and 24% in the SR group. Diverticula were identified 3.7 more frequent than accessory appendages in the AF group and 4.2 more frequent in the SR group. No difference in prevalence, size and location of LA accessory appendages and diverticula between patients with recurrent AF referred for RFCA and patients in SR was identified in the present study. The prevalence of a left common venous trunk was higher in patients with AF compared to patients in SR and proved to be an independent predictor for AF suggesting that it

is either a consequence or a predisposing factor. The prevalence of LA shapes was similar in patients with AF compared to patients in SR. Absence of a statistical significant difference in size, location and prevalence of diverticula and accessory appendages between patients in AF and SR pleads against a relation between these structures and the genesis of AF. The presence of diverticula and accessory appendages should be signalled to electrophysiologists performing RFCA

CORRELATION BETWEEN C REACTIVE PROTEIN LEVEL AND DEPRESSION

The purpose of this study was to examine the association between C reactive protein and depressive symptoms in an elderly Korean population. Among participants aged 60 or over recruited from a rural community, 224 men and 345 women without a history of stroke, angina pectoris, myocardial infarction or CRP≥20 mg/L were employed for cross-sectional analyses. As a marker of systemic inflammation, CRP was measured.In men, CRP levels had significant associations with depressive symptoms. However, in women, the association between CRP and depressive symptoms was not significant. Our findings suggest that elevated CRP levels are independently associated with the presence of depressive symptoms in elderly Korean men (Song BM, Lee J-M, Choi W et al. Association between C reactive protein level and depressive symptoms in an elderly Korean population: Korean Social Life. *BMJ* Open 2015;5: e006429. doi:10.1136/bmjopen-2014-006429. Epub 2015 Feb 3).

EFFECT OF TRANEXAMIC ACID USE ON POSTOPERATIVE BLOOD LOSS IN TOTAL KNEE ARTHROPLASTY (Abstract). **Aim**: To monitor the effect of tranexamic acid use (Exacyl) on postoperative bleeding (aspiration), autologous blood transfusion (autotransfusion), allogeneic blood transfusion and postoperative anemia (difference between preoperative and immediate postoperative hemoglobin levels) in total knee arthroplasty. **Material and methods**: This retrospective observational study was conducted on a sample of 457 patients who underwent endoprosthetic knee arthroplasty in the interval January 1, 2008-July30, 2014 at the Traumatology-Orthopedics Clinic of the Iasi Rehabilitation Hospital. The mean age of the study group was 66 years (range 32-84 years), 74.4% were female, 39.8% presented *varus* and 6.1% *valgus* malalignment. The study group was subdivided into two groups: **Group 1** served as controls and underwent surgery without the administration of tranexamic acid and **Group 2** received tranexamic acid. **Results:** In group 1 the average amount of blood lost was significantly higher than in group 2, 1168.94 ml *vs* 452.9 ml ($p < 0.001$). The use of a cell saver was required in 70% of group 1 patients with an average amount of auto transfused blood of 480.70 ml, significantly more frequent and in greater amounts than in group 2 (below 10%) with an average of 15.05 ml ($p < 0.001$). In this study tranexamic acid had not a statistically significant favorable effect on blood transfusion requirements and anemia syndrome. **Conclusion:** Tranexamic acid has a favorable effect on postoperative blood loss and its associated complications, with a favorable impact on both early clinical and functional recovery. **Keywords:** TRANEXAMIC ACID, TOTAL KNEE ARTHROPLASTY, TOURNIQUET, BLOOD LOSS.

Knee osteoarthritis is one of the most common causes of pain and loss of joint function, the risk of disability being as high as that attributable to cardiovascular diseases and higher than in any other disease in the elderly (1). The disease is more common in women (2). In the advanced stages of knee osteoarthritis endoprosthetic arthroplasty is the gold standard treatment, the technique being customized according to the associated deformity and individual joint architecture (bone and ligaments) (3).

The use of a tourniquet induces local fibrinolysis in the operated lower leg and increased fibrinolytic activity causes significant postoperative blood loss. Blood loss causes such postoperative complications as anemia (4), cardiovascular complications, post transfusion reactions (post transfusion shock, transfusion transmitted diseases, postoperative infection) (5.6), with a direct

impact on the early postoperative course and functional recovery. Tranexamic acid, a synthetic analogue of lysine which competitively inhibits the activation of plasminogen to fibrin (7.8) is used to reduce postoperative blood loss. The aim of this study was to assess the effect of tranexamic acid (Exacyl) use on postoperative bleeding (aspiration), autologous blood transfusion (use of cell saver) and allogeneic blood transfusion on postoperative anemia syndrome (difference between preoperative and immediate postoperative Hb levels, *D* Hb).

MATERIALS AND METHODS

The retrospective observational study was conducted on a sample of 457 patients diagnosed with advanced knee osteoarthritis who underwent endoprosthetic knee arthroplasty in the interval January 1, 2008 - July 30, 2014 at the Traumatology-Orthopedics Clinic of the Iasi Rehabilitation Hospital. The mean age of the study patients was 66 years (range 32-84 years), 74.4% of them being female. The study group was subdivided into two groups: group 1 (78.11%) - patients who were not given Exacyl and group 2 (21.89%) - patients who received intravenous tranexamic acid intraoperatively and immediately postoperatively.

Also evaluated was blood loss depending on the presence or absence of frontal plane deformities, as evidenced by the calculation of hip-knee-ankle (HKA) angle on long leg X- ray (fig.1.a, b). 53.6% of the patients had proper knee alignment, while varus and valgus malalignment was present in 39.8% and 6.1%, respectively.

Sagittal plane malalignment, in flexum, was associated with varus misalignment in 97% of the cases, being the sole finding in only two cases. Of the study patients with genu varum 44% presented a mild deformity of 8 degrees and 18% of over 15 degrees. In genu valgum patients, the three categories were in almost identical percentages.

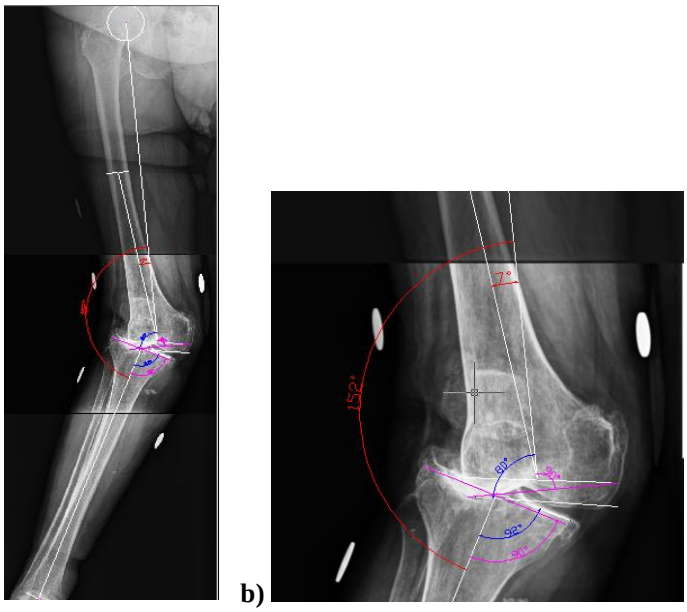

Fig. 1. a) Preoperative planning: Digital long leg X-ray of the lower limb in upright position; b)Advanced secondary knee osteoarthritis on *genu valgum* (HKA- 152^0)

RESULTS

1. **Aspiration:** Comparing the blood loss in the two groups we found a statistically significant difference ($p < 0.001$). If in group 1 the average blood loss was of 1168.94 ml (highest: 4150 ml), the analysis of data from group 2 showed an average blood loss of 452.9 ml (highest: 1100 ml) (fig. 2.) Blood loss was not influenced either by age ($p = 0.336$) or sex parameters ($p = 0.512$).

2. **Autotransfusion**: The need for a cell-saver and the amount of autotransfused blood were significantly higher in group 1 ($p < 0.001$). In group 1 a cell-saver was used in 70% of the cases and the average amount of autotransfused blood was 480.70 ml. In group 2 the average amount of autotransfused blood was of only 15.05 ml, and cell saver was used in less than 10% of patients.

3. **Blood Transfusion**: The difference between the two groups was not statistically significant ($p = 0.436$). A lower rate of allogeneic blood transfusion was recorded in group 1 (20% of cases, average amount 68.91ml) compared to group 2 (32% of cases, average amount 99.5ml).

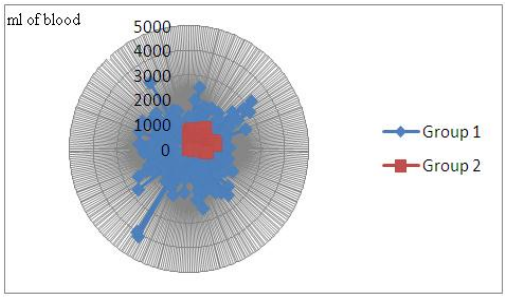

Fig. 2 Graphical representation of blood loss in the two study groups

4. **Anemia syndrome**: Mean *D Hb* was 3.27 mg/dl in group 1 and 2.74 mg/dl in group 2.The highest level was 8.10 mg/dl in group 1compared to 4.90mg/dl in group 2. Despite the values differed, the difference did not meet statistical significance ($p = 0.514$)

5. **The presence of deformities:** These variables for quantifying blood loss were also checked within the context of present or absent joint deformities, without noticing significant differences (tab. I). We noted that frontal plane deformities greater than 15 degrees were often associated with an increase in the amount of blood loss.

TABLE I

Average values of blood loss variables according to the presence/absence of diformity

Diformity Y N		No	Mean	Std. Deviation	Std. Error mean
Aspiration	No diformities	245	1001.14	597.456	38.170
	Diformities	212	1025.09	604.920	41.546
Autotransfusion	No diformities	245	357.22	388.491	24.820
	Diformities	212	403.75	387.336	26.602
Transfusion	No diformities	245	77.55	158.522	10.128
	Diformities	212	73.35	149.278	10.252
Hb difference	No diformities	245	3.0718	1.31196	0.08382
	Diformities	212	3.2521	1.24505	0.08551

DISCUSSIONS

Endoprosthetic knee arthroplasty is accompanied by minimal intraoperative bleeding due to the use of pneumatic tourniquet but by important postoperative blood loss.

This study shows that the use of tranexamic acid results in a significant decrease

in postoperative blood loss and hence in the use of cell saver, but has no impact on allogeneic blood transfusion. Our results are in agreement with literature data in terms of the amount of blood collected during suction drainage (4,7,9,10-12) but not in terms of the amount of blood needed for allogenic blood transfusion (11,12). In our study group the amount of transfused blood did not differ significantly between the two groups, the decision to resort to this therapy being more frequent in group 2, probably due to the fact that cell-saver in more rarely used in this category of patients. It is worth mentioning that although in group 2 the average blood loss was small, anemia syndrome was not statistically more significant in group 1. This mismatch between the amount of drained blood and postoperative anemia raises the suspicion of an additional blood loss. Sehat (13) speaks of a hidden blood loss of 700 ml, probably from hematoma formation.

Tranexamic acid, a synthetic inhibitor of fibrinolysis which acts by competitively blocking the lysine binding sites on plasminogen (7), reduces blood loss and financial cost in orthopedic surgery (hip and knee replacement surgery, spinal surgery) (4,9) and cardiovascular surgery (cardiopulmonary bypass) (14) but only insignificantly the hidden blood loss. This phenomenon probably represents the extravasations of red cells after tourniquet release, hemostasis being by primary hemostatic mechanisms, before fibrinolysis has any effects (15).

CONCLUSIONS

Our study highlights the importance of using tranexamic acid in knee arthroplasty as it significantly decreases the postoperative blood loss and financial cost given the fact that the use of cell-saver is less frequently required. This research demonstrates that tranexamic acid does not have a significant impact on allogeneic blood transfusion and anemia syndrome. Tranexamic acid is an essential drug product in total knee arthroplasty as it reduces postoperative blood loss and its associated complications, with a favorable impact on early recovery of joint function.

ANTIMICROBIAL ROLE OF FILAGGRIN-2 PROTEIN

Filaggrin-2 (FLG2) is a water-insoluble 248 kDa S100 fused-type protein found in the upper epidermis and eccrine sweat glands. A study by Hansmann *et al.* tested the antimicrobial activity of filaggrin-2 against *Pseudomonas aeruginosa* and other Pseudomonads and found that recombinant FLG2 C-terminal protein fragments have potent antimicrobial activity against *P. aeruginosa* and after cultivation of *P. aeruginosa* on stratum corneum, antimicrobially active FLG2 fragments are released from insoluble material by the bacteria themselves. These FLG2 C-terminal fragments have an alternative mode of action different from most other antimicrobial peptides, as they do not induce pore formation, but membrane blebbing. According to Hansmann et al., FLG2 fragments interfere with bacterial replication, inhibit their growth on skin surfaces and contribute to the skin's antimicrobial defense, explaining why *Pseudomonas* infections of healthy skin are very rare. Also, the absence of filaggrin 2 at certain body surfaces and in the case of burned skin seems to be responsible for the higher susceptibility to these infections. The study concluded that FLG2 C-terminal fragments could represent new *Pseudomonas*-targeting antimicrobials (Hansmann B, Schröder JM, Gerstel U. Skin-Derived C-Terminal Filaggrin-2 Fragments Are Pseudomonas aeruginosa-Directed Antimicrobials Targeting Bacterial Replication. *PLoS Pathog*. 2015;11(9):e1005159. doi: 10.1371/journal.ppat.1005159).

ETHICAL AND DEMOGRAPHICAL ISSUES IN SCREENING FOR CERVICAL CANCER –AN OUTLINE IN NORTH EASTERN REGION OF ROMANIA (Abstract)**: Aim**: This study complements the national screening program for cervical cancer, implemented in Romania. **Material and Methods**: Inclusion criteria for this program of active detection of cervical cancer are women aged 25 to 64 years and exclusion criteria were other age groups and the diagnosis confirmed of cervical cancer. The testing was free and used the method of colored cervical smear Pap. **Results**: In 2013, 23.680 women were tested, that means only 10.13% of the total female population eligible for screening. In 2014, the test group was 6337 (one smear required retesting), of which 5852 were negative results and 484 positive results. Squamous cell abnormalities were detected in 433 women (6.84% of total group who attended the screening). Cervical smears with atypical squamous lesions were present at the most women included in the screening, regardless of age group (67.43%). The screening detected 21 lesions HSIL (4.84%), 2 HSIL with suspicion of invasion (0.46%) and 5 lesions of squamous carcinoma (1.15%). **Conclusions**: The presence of a small number of people compared to the female population eligible to the test screening may show the need for a better spread of notions about th screening and the afferent national program, for the population in northeastern Romania, considering the ethical issues that this test assumes. **Keywords**: CERVICAL SCREENING, CANCER, ETHICS, CERVICAL SMEAR, HUMAN PAPILLOMAVIRUS.

Cervical cancer is the fourth in frequency between the woman`s malignancy worldwide and the seventh of all cancers in both sexes, with 528,000 new cases detected in 2012, as GLOBOCAN reported. Regarding mortality, it is estimated 266,000 annual deaths worldwide in 2012, representing 7.5% of all deaths in women (1).

In the European region, Romania ranks first in the incidence and the mortality of cervical cancer. Regarding the incidence, it was 39.4% ooo in 2012, according to GLOBOCAN, with 4343 new cases registered, a standardized age rate of 28.6 and a cumulative risk (0-74) 2.8. The distribution by age showed that the most affected were women 50-54 years (83.3% ooo), then those 55-59 years (80.9% ooo) (2).

There is a regional variation in the incidence of cervical cancer, with higher rates of over 30% ooo women in Maramures, Hunedoara, Arad, Constanta, Timis, Mehedinti, compared with rates below 10%ooo recorded in Ilfov, Bucharest and Vrancea (3).

Regarding the mortality, its values were 17.3% ooo in 2012, according to GLOBOCAN, with 1909 deaths, a standardized age rate of 10 and a cumulative risk (0-74) 1.2. Most deaths were recorded among women in the 70-74 years age group (39.2% ooo), then those 65-69 years (38.2% ooo) (2).

Cervical Intraepithelial Neoplasia (CIN) is a precancerous condition that may exist in one of three stages: CIN1, CIN2 and CIN3. If it is untreated, CIN2 or CIN3 (together CIN2 +) can progress to cervical cancer (4).

It is estimated that approximately 1-2% of women have CIN2 + every year. This rate is reported to be close to 10% of HIV-positive women (5).

Standard screening test is colored cervical smear Pap, and when cytology results are positive for CIN, the diagnosis is based on subsequent colposcopy, biopsy of suspicious lesions, followed by treatment only when CIN2 + lesions was confirmed by histopathology. This traditional method of screening requires high-skilled human resources and a substantial amount of laboratory equipment. In countries with low and medium socioeconomic level, because of the high cost of such screening programs based on cytology, national coverage is very low. Further, the monitoring of women with positive cytologic test and their subsequent testing by colposcopic and biopsy requires resources and trained personnel, whicih is a major problem in many such regions. Other blockages in cytology-based screening programs includes long distances between the woman's residence and equipped hospitals or clinics. An alternative approach to the detection and the treatment of lesions of CIN may be the method "Screening and Treatment" ("screen-and-treat"), where the treatment decision is based on a screening test rather than a histologically confirmed diagnosis of CIN2 + (4).

Molecular epidemiology data showed in 1991 that human papilloma viruses (HPV) are the main etiologic agent of cervical cancer, however, only in 1997 was established this fact. The study of HPV carcinogenic role continues to be a priority in research on the molecular biology of cervical cancer, especially as the number of viral genotypes identified and characterized is rising. According to a study of the female population in the North-East of Romania (Iasi), HPV16 was the prevalent oncogenic genotype (43.12%), followed by HPV18 (10.34%) and HPV31 (10.34%), and the distribution of age groups showed that the percentage of HPV positive patients was approximately the same (65% in the 17-29 years, 66.15% in the 30-39 years and 70.83% in the 40+ years). The authors of this study concluded that, although cytological screening test will not be replaced by HPV, the results on genotypes circulating will be used to develop an algorithm for effective monitoring and proper management of this type of infection (6).

Cervical Neoplasia has a progressive development, slight dysplastic changes progressing to severe dysplasias, then to carcinoma *in situ*, and without therapeutic intervention, to an invasion of squamous cell carcinoma. Screening is one of the methods of prevention (in the literal sense

of the word, screening is a protection against the danger), being a test of orientation that allows presumptive identification of the people affected previously by unknown diseases or who are exposed to risk factors. The success of screening methods and the increase of women's compliance on cervical cancer measures of prevention encourages the health systems makers to make these methods more accessible (7).

MATERIAL AND METHODS

The study comes as a complement to The National Screening Program for Cervical Cancer, implemented in Romania. *Criteria for inclusion* in this program of active detection of cervical cancer are women aged between 25 and 64 years and *criteria for exclusion* were the other age groups and the confirmed diagnosis of cervical cancer. Testing was free and used the cervical colored smear Pap method.

The program started in October 2012, and the number of women tested by the end of that year was 2915. In 2013, 23,680 women were tested, compared with eligible women population for cervical screening, of 233.615 (census provided by those networks validated until the present and it has been included in the budget estimates for 2013, as it stated in official documents of the Iasi Regional Oncology Institute) (10.13% of the total tested).

Total group of patients tested in 2014 was 6337 (1 smear required retesting), of which 5852 results were negative and 484 results were positive. In the first quarter were tested 2355 women (37.16% of the total group), in the second quarter were tested 1713 women (27.03%) and in the third quarter were tested 1119 women (17.66%) and in the last quarter of 2014 were tested1150 women (18.15%).

The statistical analysis was performed using these software: MS Excel 2010 and EPI/ INFO 7.

RESULTS

The distribution by age of the women group who presented at the IRO, for cervical smear collection indicated a preponderance of women by 40-44 years (936 - 14.77%) and 35-39 years (927 - 14.63%), and the least represented age group was the women by 50-54 years (587 - 9.26%) (fig. 1).

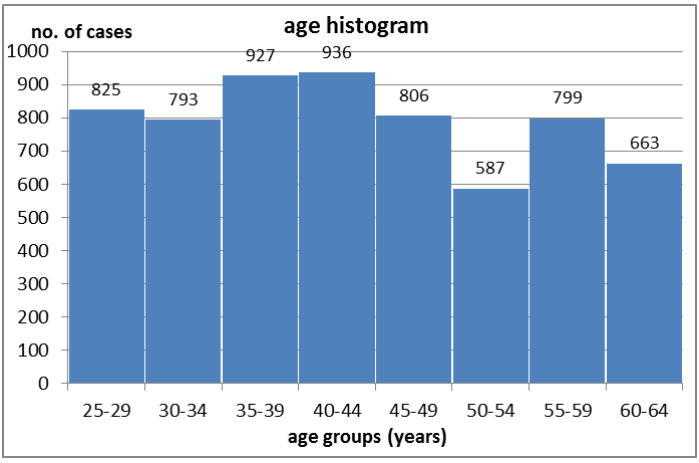

Fig. 1. Age histogram

Of all smears examined, 8.29% were positive for various neoplastic and atypical lesions (485 patients). The distribution by age groups of positive smears showed a predominance in women by 40-44 years and 55-59 years (15.87% each). Of the total harvested smears, the positive ones had the highest frequency in women by 55-59 years (9.64% of total smears collected at this age group) and 50-54 years (8.35%) (fig. 1, tab. I).

Squamous cell abnormalities were detected in 433 women (6.84% of total screening group). Cervical smears with atypical squamous lesions were present at the most womenincluded in the screening, regardless of age group (67.43%). Even at 25-29 years, they (ASC-US) accounted for 56.51% of all smears. They were most often present in women by 55-59 years (73.91%). LSIL were present in 9.69% of the total group, and most often in women by 55-59 years (11.59%). It is noted that LSIL with atypical HPV (8.77% of total) were most often present in young women by 25-29 years (34.21%). The screening detected 21 HSIL lesions (4.84%), 2 HSIL with suspicion of invasion (0.46%) and 5 squamous cell carcinoma lesions (1.15%) (fig. 2).

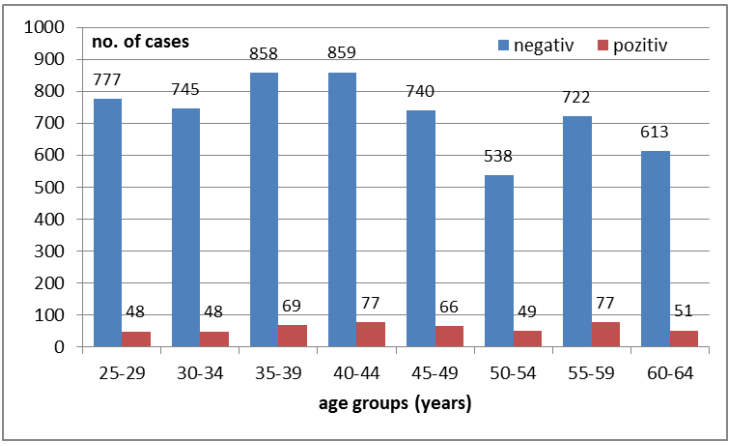

Fig. 2. Results of cervical screening

With reference to *abnormalities of glandular cells* (ACG), the harvested cervical smears showed 51 lesions (0.8% of all women participating in screening),

being more common in women by 35-39 years. Was found a case of adenocarcinoma in the 60-64 years age group and 2 anomalies in the favor of neoplasia (ACG-FN). However, most of these lesions types were ACG endocervical - NOS (significance unspecified) - 56.86% of ACG total lesions (fig. 3).

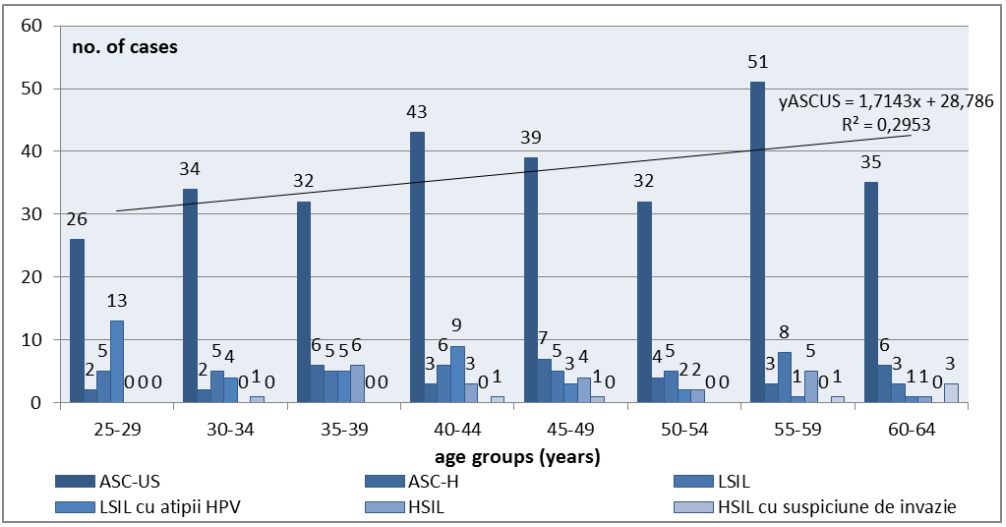

Fig. 3. Age group distribution of the anomalies of squamous epithelial cells in Pap's test of the patients

DISCUSSION

The mission facing doctors specialists and family physicians, refers to presenting the benefits of the screening test, the patients included in the list or who come to medical examination. However, must be considered that the Pap test of cervical smear can have false negative results or false positive results or can be inconclusive, therefore, when planning to guide the patient to screening, doctors should reflect the ethical responsibilities of this test (8, 9).

Some researchers in social psychology and in ethics have mentioned the existence of a degree of emotional involvement of patients, reflected in particular by increased anxiety related to performing cervical screening. False positive results can cause importantly distress to patients, including on unnecessary treatment, the false negative results may cause emotional changes when diagnosis will be made later, and the false assurance of the woman that it would be in a state of full health. These negative effects of screening are probably quite frequent and can be the cause of anxiety and a long-term distress. To minimize these problems, the patient should be well informed and involved in cognitive processes to really take the best decision regarding the test screening (8, 10).

It was found that the reduction in incidence and mortality rates of cervical cancer was more pronounced in women who were tested for HPV compared to those who carried out only cytology followed by colposcopy. Treatment may still be overestimated in groups with high prevalence of HPV and therefore, this can get greater harm at the individual level. Adding col-

poscopy, however, require a second visit to the specialist. However, in countries where there is already an adequate strategy for high quality screening, cytology (done in women with ASC-US or other more advanced lesions) is followed by colposcopy, regardless that the HPV test was previously performed (4) .

The general reaction of women to a positive test screening or HPV testing was one of distress, anxiety and anger. Women have described that they felt shocked at receiving the news that they had a genital infection, that had previously acknowledged a little or not at all, due to lack of symptoms. This was combined with anxieties about the risk of cancer and concerns about further investigation or treatment for cervical intraepithelial neoplasia (CIN) and about fertility. These problems have been common in the groups of women with abnormal Pap smears, even in the absence of HPV testing. Some women have described the degree of anxiety associated with intrusive thoughts and somatic reactions in the period in which they received their first screening test result. Much of the concern that arose related to the test result was positive was on the issue of sexual transmission of infection, this distress affecting their social, emotional and behavioral dimensions. Shock, embarrassment to the partner, feeling of shame and blaming, the stigma of having a sexually transmitted disease were common reactions in women with a positive Pap test, they used terms such as unclean, dirty, embarrassing, disgusting, immoral. Searching of a case and trying to understand what caused the positive result was a frequently behavior in women with abnormal Pap smear. Some women described the feeling of annoyance that a previous partner would be infected with a serious and carcinogenic virus, others can be considered guilty of acquiring infection because of negligence or an previously promiscuous behavior. Other women may accuse breach of trust in a partner who subsequently proved unfaithful. However, most of these women finally say that the source of the infections is another one, such as a previous partner (11, 12, 13).

The social, cultural, especially economic, religious and historical differences under the pressure whose live the women from anywhere in the world, reflect deeply on the issues and the ethical dilemmas that they carry with them when they are put in a position to consult a doctor on a gynecologist or gynecologic oncologist problem. The doctor must learn to recognize the social and ethical particularities of the community it cares for. These issues include the right to knowledge (the right to know), and inequalities in health insurances and services from that the patient can benefit (14).

Contrary to many significant advances purchased, the cervical cancer screening still may be associated with adverse events in national screening programs, requiring a balanced view of risk - the benefit of participating women. Thus, Weller notes that it would be appropriate to cover the following areas: social inequality, informed choice, the cost of screening when screening did not go well, given the new challenges of HPV testing and HPV vaccination (15).

Adding the answers to these dilemmas in a time capsule, along with the successes and the shortcomings of the program, known from past and present, can be interesting to anticipate the exciting directions and the ethical challenges that cervical

cancer screening will be up to future generations.

CONCLUSIONS

Through our study, we found that a small number of people compared to the female population eligible, was present at the screening test, which shows the need for better spread of notions screening and the national program related, on the North-East Romania population, taking into account the ethical issues of this test.

ANIMAL MODELS OF OSTEOPOROSIS: CRITICAL CONSIDERATIONS (Abstract) Animal models are necessary to study the pathogenic mechanisms of osteoporosis and to test new drugs. The aim of this study was to critically evaluate the experimental models of osteoporosis in rats or mice for an appropriate use in new drug testing. There are five distinct groups of experimental methods for inducing osteoporosis: surgical, immobilization, pharmacological, dietary and transgenic models. Combinations such as ovariectomy plus immobilization or administration of glucocorticoids or diet changes, have the advantage of reducing the time when bone mass loss becomes apparent, especially for cortical bone. No experimental model can reproduce human osteoporosis; therefore, for testing new drugs the selection of a suitable model is essential. **Keywords**: OSTEOPOROSIS, EXPERIMENTAL MODELS, RAT/MICE, DRUG TESTING.

The multifactorial character of this disease, its incompletely known pathogenesis, the negative impact on the quality of life, with a high incidence of complications and mortality, are arguments for the need of further researches in this field (1, 2). Osteoporosis is characterized by low bone mass and deterioration in bone tissue micro architecture, with a consequent increase in bone fragility and susceptibility to fracture. Affecting both genders, with a higher incidence and prevalence in women, osteoporosis is a progressive systemic skeletal disease with a great social impact, associated with long-term implications, severely decreased quality of life and high mortality. Clinical studies involve high costs and need long periods of surveillance; therefore, experimental animal models play an important role in osteoporosis research, especially for testing new drug treatments (3).

The aim of the study was to critically evaluate the experimental models of osteoporosis in rats or mice for an appropriate use in new drug testing. Data sources were relevant preclinical studies on experimental osteoporosis from PubMed, published in English or French, from 1980 up to March 2015. Searched terms included "experimental osteoporosis", "rat/mice", and "biomar-kers". From 4.355 papers about experimental osteoporosis published in the interval 1980-2015, there were selected 65% of the original articles and critical

reviews (1.947 papers on rat models and 885 papers on mouse models) describing the methods for inducing osteoporosis and biomarkers. The studies with incomplete data about the criteria for osteoporosis, letters to the editors and commentaries were excluded. The methods used for inducing osteoporosis in rats or mice were: surgical intervention (4-7), immobilization (7-9), drug-induced osteoporosis (10-17), dietary interventions (18-21) and transgenic models (22-24).

BIOMARKERS IN OSTEOPOROSIS

Osteodensitometry, a non-invasive method, evaluates the bone loss which occurs immediately after ovariectomy (bone resorption exceeds bone formation); later, bone remodeling reaches a steady state where bone formation and bone resorption are in balance (3). The markers that indicate cancellous bone loss after ovariectomy are: earliest time of bone loss (14 days for the proximal tibial metaphysis, 60 days for lumbar vertebral body, 30 days for femoral neck), time of 50% bone loss (30-60 days for the proximal tibial metaphysis, 180-270 days for lumbar vertebral body and for femoral neck), earliest to achieve steady state (90 days for the proximal tibial metaphysis, 270 days for lumbar vertebral body and for femoral neck), and earliest decrease in bone strength (7). The markers that indicate cortical bone loss bone after ovariectomy are the enlargement of the marrow cavity (the site for bone loss analysis is the inner half of the shaft adjacent to the marrow), the earliest changes in the femoral and tibial cortex (90-120 days) and steady state (180 days) (4).

Ovariectomy in mice is not very popular because the markers that point the changes in cortical bone are not clear defined (4). The trabecular and cortical response to ovariectomy are variable among inbred mouse strains, which is in favor of the hypothesis that pre- and postmenopausal bone activity is partly genetically regulated (5).

Comparative with ovariectomy, in the immobilization model the earliest time of cancellous bone loss is 14 days for the proximal tibial metaphysis, 30 days for the distal tibial metaphysis and the time to achieve steady state is 126 days for the proximal tibial metaphysis and 45 days for the distal tibial methapysis (3). In the immobilization model, the earliest time of bone loss in the cortical bone is 21 days for the femoral cortex and 42 days for the tibial cortex; the time of 10% bone loss is 26 weeks (3).

Other biochemical markers useful in evaluating osteopenia are: blood and urinary levels of phosphorus, calcium, magnesium, markers of bone formation (alkaline phosphatase, osteoclacin) and markers of bone resorption (urinary type I collagen cross-linked N-telopeptides, pyridinoline, tartrate-resistant acid phosphatase).

Histomorphometry, an invasive method, provides information about: number of osteoblasts, osteoclasts, osteocytes, active osteoblasts relative to bone perimeter, trabecular thickness (3).

Mechanical strength testing, an invasive method, assess the mechanical quality of the bone and is applied to diaphyses of long bones (three-point bending, 4-point bending, torsion), vertebras (compression testing), femoral head (cantilever testing) (3).

SURGICAL METHODS FOR INDUCING OSTEOPOROSIS

Bilateral ovariectomy versus orchiectomy is the surgical intervention preferred by most researchers for obtaining osteoporosis (rat, 1691 *vs.* 99 studies; mice, 491 *vs.*

28 studies). Ovariectomy in rats, the most frequently used technique as model for postmenopausal osteoporosis, simulates the clinical criteria of the osteoporotic human skeleton and reproduces the response of therapeutic drugs. Orchiectomy induces androgen deprivation which promotes an osteoporotic model (5).

Alternative interventions in rats for obtaining osteoporosis are hypophysectomy (3 studies), pinealectomy (3 studies) or below-knee amputation (6 studies).

IMMOBILIZATION FOR INDUCING OSTEOPOROSIS

Immobilization for inducing osteoporosis may be realized by non-invasive methods such as: tail suspension (54 studies on rats, 33 studies on mice), confinement (1 study on rats, 1 study on mice) or administration of botulinum toxin (9 studies on rats, 4 studies on mice). Surgical resections of spinal nerve (3 studies on rats), tendon (4 studies on rats) or spinal cord (13 studies on rats, 3 studies on mice) are invasive methods. Immobilization combined with ovariectomy provides a severe bone loss in a shorter period than either method alone (9).

The favorite immobilization model is tail suspension because it causes hypertension and adrenal hypertrophy (6, 7). Botulinum toxin type A-induced immobilization determines similar osteoporotic effects as ovariectomy (8).

DRUG-INDUCED OSTEOPOROSIS

There are several drugs used for inducing osteoporosis (tab. I): corticosteroids (25 studies on rats; 20 studies on mice), gonadotropin-releasing hormone (GnRH) agonists (4 studies on rats) or aromatase inhibitors (1 study on rats). Corticosteroid-induced model of osteoporosis (with Prednisone or Dexamethasone) has a good correlation between drug administration and bone loss (10, 12). The administration of Buserelin, a GnRH agonist, leads to estrogen deprivation, resulting in bone loss similar to bilateral ovariectomy (15). The administration of aromatase inhibitors (Vorozole) in aged male rats induces a net trabecular bone loss in the appendicular and axial skeleton (16).

Association of methods induces osteoporosis more rapidly, using lower doses. One schedule starts 2 weeks after ovariectomy in rats, with dexamethasone 0.3 mg/kg b.w./day once every two weeks (17).

TABLE I

Drugs and schedules for inducing osteoporosis (rats or mice)

Drugs	Rat		Mouse	
	dose	schedule	dose	schedule
Prednisolone (mg/kg)	3.5 mg	s.c., daily, 4 wk	1.4-2.1 mg	s.c., daily, 4 wk
Dexamethasone (mg/kg)	2.5mg	i.m., x2/wk, 9 wk	50 mg	i.p., daily, 5 wk
Buserelin (µg/kg)	25 µg	s.c., daily, 4 wk	-	-
Vorozole (mg/kg)	17 mg	p.o., daily, 15wk	-	-

wk: week.

DIETARY CHANGES FOR INDUCING OSTEOPOROSIS

Dietary changes are non-invasive methods less used to obtain osteoporosis in animals: diet deficient in Ca^{2+}/vitamin D_2/D_3 combined with ovariectomy for

achieving osteoporosis more rapidly (18); prolonged Mg^{2+} deficiency (19); high fat diet (20); excessive alcohol (21).

TRANSGENIC MODELS FOR INDUCING OSTEOPOROSIS

Transgenic models of osteoporosis (36 studies on rats, 305 studies on mice) are useful for understanding the pathogenesis and for identifying new therapeutic targets for the treatment of osteoporosis. These models use transgenic mice carrying the human genomic region (e.g., TghuRANKL mice carrying receptor activator of NF-kappaB ligand RANKL – a region which plays a key role in osteoclast-induced bone resorption) (22), transgenic mice that inappropriately expresses the cytokines (e.g., IL-4 and IL-13 – involved in the regulation of bone remodeling) (23) or premature accelerated aging in mice (a suitable model for involutional osteoporosis and its treatment) (24).

CONCLUSIONS

In our observations we aimed at demonstrating that animal models have a crucial role in osteoporosis research, especially in the development of new therapeutic strategies. Combination of methods (e.g., ovariectomy + immobilization, + glucocorticoid or + diet changes) has the advantage of reducing the time when bone mass loss becomes apparent, especially for cortical bone. There is no ideal animal model for osteoporosis; the selection of an appropriate model is the key to well-done promising researches. Essential in selecting the best model for research and especially for testing new drugs for the treatment of osteoporosis is to know the limits and strengths of various animal models.

TRAUMATIC SCAPHOLUNATE DISSOCIATION- CASE REPORT (Abstract): Perilunate injuries occur after an impact trauma to the wrist. The recognition of these lesions and immediate treatment are the two essential conditions to ensure the best possible outcome. The first therapeutic step is the restoration of anatomical joint relationships of the carpus followed by percutaneous pinning or internal fixation required for maintaining the congruence this segment. Despite correct diagnosis and approach in these cases the prognosis is often encumbered by decreased range of motion, loss of grip strength and finally the onset of osteoarthritis. Scapholunate dissociation is the most frequent pattern of carpal instability. We report the case of a 53-year-old woman diagnosed with scapholunate dissociation resulting from an injury caused by fall from the same level on the outstretched right hand (dominant hand). Surgery was performed 48 hours post-injury and consisted in external reduction followed after the restoration of the anatomical joint relationships in the right wrist by percutaneous pinning. Postoperatively the wrist was immobilized in brachipalmar cast for 8 weeks and arthrosynthesis pins were removed. The patient was reassessed at 6 months postoperatively by clinical and radiological evaluations and the functional outcome was good. **Keywords:** SCAFOLUNATE ANGLE, CAPITOLUNATE ANGLE, TERRY THOMAS SIGN, SCAPHOLUNATE DISSOCIATION, ROTATORY SUBLUXATION OF THE SCAPHOID.

Scapholunate dissociation is a ligament injury of the wrist which causes the loss of normal alignment between the scaphoid and lunate bones due to partial or complete injury to the scapholunate interosseous ligament and extrinsic ligaments with a role of secondary stabilizers of this segment. This pathology is frequently under diagnosed being misdiagnosed as simple wrist sprain. The occurrence of carpal instability leads to biomechanical changes and favors the occurrence of arthrosic lesions and ultimately of scapholunate advanced collapse finally (SLAC) wrist. The dissociation is also accompanied by rotatory subluxation of the scaphoid bone. Wrist arthroscopy allows the visualization of the scapholunate space and has become a standard method useful for both the diagnosis and management of this condition.

CASE PRESENTATION

A 53-year-old woman presented to the emergency unit following an injury occurred on the same day by fall from the

same level on the right hand (dominant member) with the wrist in hyperextension. Physical examination revealed a moderately diffuse edema over the dorsal aspect of the right wrist and hand, diminution of grip strength and antalgic restriction of active movements. The scapholunate interval was identified by palpation as the point of maximum pain intensity and the scaphoid shift test revealed the presence of scapholunate instability. Neuro-vascular examination revealed no changes in the radial artery and median nerve territory. The patient had a non-pathological personal history and routine laboratory investigations were within normal ranges.

As first-line imaging investigation bilateral wrist X-rays in anteroposterior, lateral and oblique views were preformed, later supplemented by CT scanning. Anteroposterior X-rays showed the increase in scapholunate interval to 4 mm (positive Terry Thomas sign) and rotatory subluxation of the scaphoid. At the level of radial styloid apophysis a fracture line without displacement was identified. Profile X-ray revealed a scapholunate angle value of 80° (normal 30-60°) and a capitolunate angle of 40° (normal 20°) (fig.1).

For comparison X-rays of the contralateral wrist were performed and these showed a scapholunate space within normal range and the correct orientation of the semilunate and scaphoid bones (fig. 2).

Fig. 1. X-ray appearance of the right wrist

Fig. 2. Normal articular relationships in the contalateral wrist

Standard radiological examination showed the presence in both wrists of a risk factor reported in the literature, namely ulna minus configuration (1).

Computed tomography confirmed the diagnosis of scapholunate dissociation showing an unevenly increased scapholunate joint space, more pronounced posteriorly, of up to 7 mm, anterior semilunate subluxation, and the presence of a bony fragment of 4/2/ 4mm resulting from ligament avulsion. Similar millimetric frag-

ment were seen on the posterior margin of the radial epiphysis (1.4 / 3.4 / 2.5 mm) and volar aspect of the distal radioulnar joint adjacent to the radius (2/1.4/2.8 mm) (fig. 3, 4).

The intervention consisted of percutaneous pinning under locoregional anesthesia (supraclavicular block). The semilunate was repositioned by wrist flexion followed by temporary stabilization to the radius with a 1.2 mm Kirschner pin. Scaphoid position was corrected by wrist-extension maneuver and was maintained with two pins percutaneously driven into the semilunate and from the scaphoid into the big bone, respectively (fig. 5).

Postoperatively the wrist was immobilized in neutral position with a brachipalmar cast for 8 weeks. Periodic radiological controls confirmed the preservation of normal joint relationships and the correct pin positioning which were removed after 8 weeks.

Clinical and radiological reassessment at 6 months postoperatively showed regional osteoporosis without indicating the onset of avascular necrosis at the carpal bones but dorsal intercalated segment instability (DISI) deformity was observed. Grip strength in the right hand was determined and was 70% of the contralateral side. Capito-lunate angle was 30^0, scapholunate angle 60^0, active flexion 50^0, and active extension 60^0 (fig. 6).

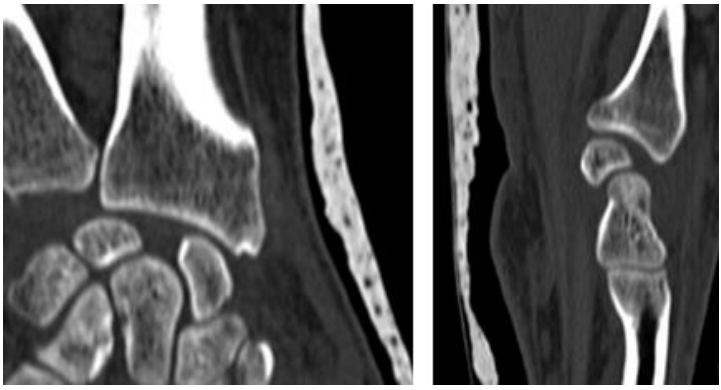

Fig. 3. CT scan of the right wrist

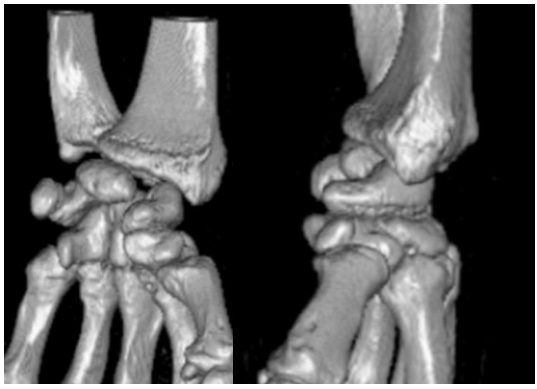

Fig. 4. Three-dimensional reconstruction of the right wrist

Fig. 5. Postoperative result

Fig. 6. X-ray control at 6 months

DISCUSSION

Intracapsular ligaments of the wrist are classified into intrinsic and extrinsic. Scapholunate and lunotriquetral ligaments are the most important intrinsic ligaments each being composed of three fascicles (dorsal, palmar and proximal). Scapholunate interosseous ligament is considered the primary stabilizer of this joint and its dorsal portion represents the area of maximum strength while the lunotriquetral ligament is more prominent on the palmar side (2).

The presence of secondary stabilizers represented by the extrinsic ligaments of the wrist makes that an isolated lesion of the dorsal fascicle of the scapholunate ligament to determine in the worst case dynamic instability of this segment (seen only on stress radiographs) without a resulting static scapholunate dissociation seen on standard radiographs (3).

In the palmar area strong radiocarpal ligaments which are secondary stabilizers are identified: the radioscaphocapitate, the radioscapholunate ligament, long and short radiolunate ligaments. The radioscaphocapitate ligament originates from the radial

styloid process, crosses the body of the scaphoid and inserts distally into the palmar aspect of the capitate bone, acting as a fulcrum around which the scaphoid rotates. The radioscapholunate ligament, also called the ligament of Testut, also has the role of stabilizing the scaphoid and neurovascular pedicle being connected with the radial artery, anterior interosseous artery and anterior interosseous nerve (4).

Scapholunate dissociation is the first stage of perilunate instability and results from injury to the scapholunate interosseous and palmar radioscaphocapitate ligaments which bring the semilunate in extension while the scaphoid flexes and pronates. Mayfield et al. describe the application of impact force to the hypothenar region of the hand with the wrist in extension and ulnar deviation as the main mechanism of action. As the impact force amplifies, the ligaments and bones of the wrist are injured in a circumferential direction around the semilunate and in the radioulnar direction (5).

Ligament injury is often accompanied by scaphoid fracture without displacement or fracture of the radial styloid apophysis. Scapholunate dissociation occurs only when injury to the scapholunate ligament is accompanied by injury to the secondary stabilizers. Incongruous joint relationships determine changes in biomechanics and load concentration at certain points resulting in the occurrence of scapholunate advanced collapse (SLAC) and development of degenerative arthritis. Patients diagnosed with scapholunate dissociation may present preexisting generalized ligamentous laxity (6).

Conservative treatment is of limited value for this type of lesion being currently abandoned due to the loss of reduction that most often occurs. Although semilunate extension can be easily corrected by wrist flexion, this will accentuate the vicious position of the scaphoid, and thus there is not an ideal position for immobilization. Surgery remains the correct option and is recommended to be performed within the first 3 days (7, 8).

If reduction is easily obtained and maintained percutaneous pinning combined with immobilization for a minimum of 8 weeks is an important therapeutic resource. Most authors recommend the use of two pins, both passed through the scaphoid and advanced into the semilunate and capitate bone, respectively. Scapholunate joint reduction can be easily achieved by the insertion of two pins into the scaphoid and lunate and used as joysticks. The intervention is facilitated by arthroscopic control. Whipple (9) reported an 85% success rate in maintaining scapholunate reduction in patients with a scapholunate interval greater by 3 mm than the contralateral wrist if surgery was performed within the first 3 months. Despite early diagnosis and correct treatment radiological revaluations reveal in over half of the operated patients the onset of wrist osteoarthritis whose treatment requires such difficult and debilitating reinterventions as proximal row carpectomy and wrist arthrodesis (10).

CONCLUSIONS

Scapholunate dissociation remains a complex pathology both in terms of diagnosis and especially of treatment. In our patient reduction by external maneuvers followed by percutaneous pinning provided good functional and radiological outcomes. No changes, such as avascular necrosis of the carpal bones were present but a dorsal intercalated segment instability (DISI) persisted.

DYNAMIC OBSTRUCTION OF THE LEFT MAIN CORONARY ARTERY OSTIUM BY A PAPILLARY FIBROELASTOMA

Benign tumours of the heart are usually detected as incidental findings during echocardiography. Most cases are intracardiac tumours, with myxoma being the most frequent entity. There are reported images of a patient with acute myocardial infarction and a concomitant extracardiac benign tumour, consisting in fibroelastoma in the aortic root. Papillary fibroelastoma is the second benign tumour of the heart. It is a rare intracardiac tumor, with rather high risk of embolization. It usually originates from the aortic and mitral valve. Extracardiac, as observed in the reported case, is very rare and searching the lesion as a cause of acute coronary ischemia identification is needed (Napp LC, Baraki H, Bredt M, et al. Dynamic obstruction of the left main coronary artery ostium by a papillary fibroelastoma. *Cardiovascular Pathology* 2014, 23: 57-58).

UROGENITAL PROLAPSE – CURRENT METHODS OF SURGICAL TREATMENT (Abstract): Several combined surgical procedures have been described, but connective tissue deficiency required the use of some "prostheses" instead of conventional methods based exclusively on correction by suture. **Aim**: Assessment of the techniques used for the repair of stress urinary incontinence (SUI) and anterior vaginal wall prolapse, as well as the incidence of intraoperative and postoperative incidents and complications. **Material and method**: The study was conducted between January 2007 and December 2011 at the 1st Clinic of Obstetrics and Gynecology Iaşi. The diagnosis was made on clinical criteria. Menopausal patients received estrogens prior to surgery. Vaginal meshes were used only in patients with grade III and IV cystocele. The patients were followed up at 1½, 6, 12 and 36 months (first local evaluation for meshes at 2 weeks after surgery). **Results:** During the study interval 400 patient with a mean age of 57.45 ±5 years (range 29 - 81 years) were surgically treated in our clinic. Of these, 150 women underwent classic surgery, 243 women transobturator tape procedure - TOT (107 TOT alone for SUI and 136 TOT combined with classic surgery), 4 women tension-free vaginal tape (TVT) procedure, and 3 patients prepubic and transobturator mesh. In 12 patients meshes with 2 or 4 arms for cystocele (7 and 5 cases, respectively) were used. Vaginal mesh extrusion was recorded in 4 patients. **Conclusions:** The use of prostheses allows a better standardization of procedures, shortening of surgical time and a better postoperative recovery, the patients being able to resume their normal activities. **Keywords**: UROGENITAL PROLAPSE, SUI, TOT, VAGINAL MESH.

Prolapse greatly affected women's personal and professional activities causing some women to adjust routines or stop activities (1). Up to 50% of multiparous women are diagnosed with urogenital prolapse and 10-20% of them require surgical treatment because of their symptoms (2). The health care impact of prolapse is likely to expand, based upon estimates of an increasing prevalence in the growing population of elderly women.

Taking into account that for the reconstructive surgeries an accurate diagnosis must be done in order to correct the defect, we can use stiches, biologic or synthetic meshes**.** The aim of reconstructive procedures is to maintain the physiological length, diameter and vaginal axes for the conservation of sexual, urinary and bowel function. The necessity of simultaneous

correction of all pelvic floor dysfunctions must have a good anatomical and functional result, and for this the physician must to know a few of surgical techniques, to take a final optimal decision for the patient.

In clinical practice we will observe that damage to the supporting tissues can cause prolapse and urinary incontinence. The deficiency of connective tissue is a favoring factor in the pathogenesis of these conditions, but also for postoperatve recurrences of urogenital prolapse. The rate of recurrences varies between 24-43% depending on surgical procedure. The involvement of connective tissue had determined the use in recent years of some "prostheses" – synthetic polypropylene meshes, which have important advantages over conventional technique exclusively based on correction by suture. This technique with meshes for recurrences was firstly used in general surgery and now has a great success in urogynecology (3). For SUI several therapeutic approaches have been tried. Nowadays transobturator sling is becoming more and more important. TOT described for the first time in Netherlands (1998), and introduced by Delorme in France in 2001, has been accepted in the US since 2003 (4).

MATERIAL AND METHODS

This retrospective and prospective study was conducted between January 2007 and December 2011 at the 1st Clinic of Obstetrics and Gynecology Iasi. The diagnosis was made on history and physical examination, without urodynamic tests. We collected a series of data from patients regarding their health status and medical history. Symptomatic anterior compartment prolapse was determined by self-report of a feeling of bulge, pressure, or protrusion or a visible bulge from the vagina. There is resulting protrusion of the vaginal wall. Anterior compartment status was assessed by the most caudal bladder point and the internal urinary meatus. Transperineal ultrasound for urethra angle and abdominal ultrasound for the bladder for chronic retention were used for some cases.

Local estrogen preparations were used to improve preoperative vaginal thinning (atrophy) for minimum three-four weeks for all women in menopause. We recommended vaginal mesh only for cystocele grade III or IV.

The postoperative course was evaluated at 1½, 6, 12 şi 36 months (first local examination for meshes at 2 weeks).

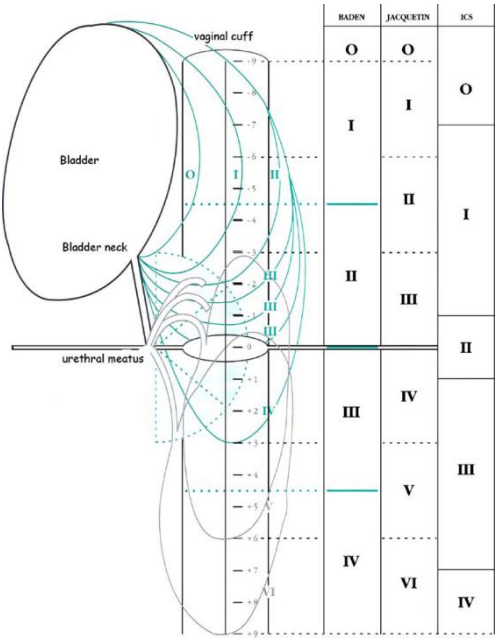

Fig. 1. Comparison cystocele quantification after Baden şi Walker, Jacquetin, International Continence Society (ICS)

The grade of anterior vaginal wall was appreciated with the patients in the lithotomy position at rest and during a cough test and Valsalva maneuver. The classification

used by us in the study was Jacqetin, which modifies the system sistemul Baden şi Walker (fig.1)

- Stage I - the leading edge descend suntil to the first 1/3 of the vagina
- Stage II – descend until the mid-vagina
- Stage III – descend at the hymen level
- Stage IV – outside the hymen

RESULTS

During the study interval a total number of 400 women were surgically treated; mean age at admission was 57.45 ±5 years (range 29-81 years). The greatest number of cases were recorded in 2008 – 108 patients (fig. 2).

The majority of patients were post-menopausal and in the 6th decade of life (fig. 3).

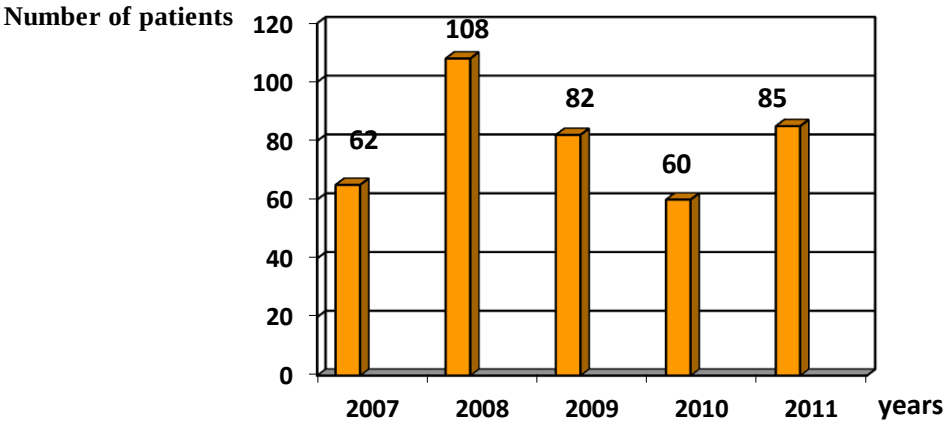

Fig.1 Distribution by years of cases

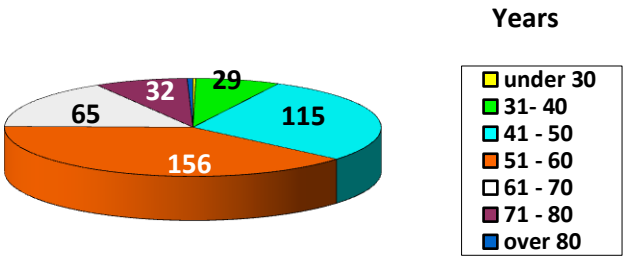

Fig. 3. Distribution of cases by age

The following surgical procedures were performed: classic pelvic reconstructive surgery (150 cases), TOT (243 cases – TOT alone for SIU in 107 women and TOT combined with classic surgery in 136 patients), TVT (4 cases) and suprapubic arc sling and transobturator mesh (3 cases). In 12 women the transvaginal repair of the cystocele was done with 2 or 4 arm meshes (7 and 5 patients, respectively) (fig. 4,5).

We mention that 25 women who had undergone previous surgery for SUI or anterior vaginal wall prolapse, had recurrence between 6 months and 5 years, and with TOT procedure in our clinic during the study interval obtained good results.

Fig. 4. Mesh with 2 arms TOT

Fig. 5. Mesh with 4 armes TOT

A small number of intraoperative complications were recorded: in 5 women the sling had a transvaginal position and the tapes were replaced during the surgery and in 2 cases the tape arrived inside the bladder during the TOT procedure and this was seen at cystoscopic examination (these were accidents durig the learning curve). As to postoperative complications, there were 2 cases with mesh exposure in the vagina – one case with insulin-dependent diabetis mellitus, one case with important atrophy (fig. 6), other 2 with vaginal mesh erosion after 6 months and 1 year, respectively, and only 1 case with erosion after mid-urethral sling. In these patients we performed the excision of the exposed mesh (fig. 7) with general and local antibiotic treatment and hormone therapy (one case with secondary suture).

Fig. 6. Mesh exposure

Fig. 7. Excision of the exposed mesh

No uterthral lesions were recorded. All patient except two had urinated spontaneously when bladder catheter was removed. After sling procedure, only 3 patients complained of persistent urine loss, but all other women – 98.78%, were satisfied with the results of surgery.

DISCUSSIONS

It was estimated that a women has an 11% lifetime risk of undergoig a single operation for urinary incontinence or pelvic organ prolapse (POP). It is considered that the risk of urogenital prolapse is duplicated in every single decade of the life, fact not supported by our study. A study estimated that the number of American women with at least one pelvic floor disorder will increase from 28.1 million in 2010 to 43.8 million in 2050. During this time period, the number of women with urinary incontinence (UI) will increase by 55% from 18.3 million to 28.4 million (5). All these underline the importance of using efficient surgical methods with a small rate of recurrence (6).

In 1996, a standardized terminology for the evaluation of pelvic organ prolapse (POP) was established by the International Continence Society, the American Urogynecologic Society, and the Society of Gynecologic Surgeons. This terminology replaced terms as cystocele, rectocele, enterocele, and urethrovesical junctions with precise descriptions relating to specific anatomic landmarks.

The first points are on the anterior vaginal wall and categorize anterior vaginal wall prolapse accordingly. Point (Aa) is a point located in the midline of the anterior wall 3 cm proximal to the urethral meatus and is roughly the location of the urethrovesical crease. Point (Ba) represents the most distal position of any part of the anterior vaginal wall. Point (C) represents either the most distal edge of the cervix or the leading edge of the vagina if a hysterectomy has been performed. Point (D) represents the location of the posterior fornix (pouch of Douglas) in a woman with a cervix. Point (Bp) is a point most distal of any part of the upper posterior vaginal wall, and point (Ap) is a point located in the midline of the posterior vaginal wall 3 cm proximal to the hymen. To record measurements, these points should be expressed in centimeters above or below the hymen. It is important for the examining individual to express the position and other circumstances of the examination (e.g., straining or not, patient flat on table or in examining chair).

Staging of Pelvic Floor Prolapse Using International Continence Society Terminology (POP Quantification):

- Stage 0: No prolapse is demonstrated. Points Aa, Ap, Ba, and Bp are all at -3 cm and either point C or D is between total vaginal length -2 cm;
- Stage I: Criteria for stage 0 are not met, but the most distal portion of the prolapse is >1 cm above the level of the hymen;
- Stage II: The most distal portion of the prolapse is less or equal to 1 cm proximal or distal to the plane of the hymen;
- Stage III: The most distal portion of the prolapse is >1 cm below the plane of the hymen but protrudes no further than 2 cm less than the total vaginal length in centimeters;
- Stage IV: Essentially complete eversion of the total length of the lower genital tract.

We did not use in practice this quantification, but it is important because it introduces a common language for all surgeons,

and much more age <60 years and preoperative POP quantification stage 3 or 4 were associated with a grater likelihood of recurrent prolapse at 1 year (7).

TOT procedure rapidly and with great succes replaced TVT technique and today is the gold standard in the surgical treatment of SUI. For understanding why this procedure was created it is neccessary to know the anatomy, and this shows us that the method is without risks because it avoids all major structures. In our clinic TOT procedure was preferred to TVT due to its shorter shorter operative time (no need of control cystoscopy after surgery) and minimal risk for bladder lesions

The treatment of pelvic static disorders might also vary depending on age, clinical conditions and sexual life prospects for the future. A comparative study of postoperative results of anterior colporrhaphy and mesh procedure showed that pain during sexual intercourse appears in 2% after colporrhaphy and in 7.3% after transvaginal repair with mesh (8). For that reason the management in our clinic recommended the use of meshes only for anterior vaginal compartment grade III and IV. Contraindication of using prosthetics for the pelvic floor are not established yet, and the interaction with bladder either. Patients must be informed about these new methods of treatment with a grate rate of anatomical repair, even though there is a risk of postoperative complications.

Data in the literature reveal that preoperative treatment for three weeks with estrogens reduce the incidence of cystitis within the first four postoperative weeks but this unexpected finding needs confirmation from larger trials. Our study supports this finding. Also tibolone, a selective estrogenic activity regulator, per vaginal administration had better results on vaginal dryness versus per os regimen (9). Some studies indicated a rate of cure about 80.64% and 87% (10,11). It seems that for our group of patients results were better – 98.78%.

CONCLUSIONS

Our study ascertains that using syntetic prosthesis allows a good standardization of procedures, decrease the operative time, a better postoperative recovery, and women resume usual activities. We reserved the technic with vaginal meshes only for cases with important anterior vaginal compartment prolapse and patients in which the techniques basesd solely on suture of destroyed structure would results in an increased risk of recurrence. In our group of patients the rate of complications was low 3.05%, possibly because of the use of preoperative local estrogens and postoperative antibiotic prophilaxis. TOT procedure offered to our patients a good urinary continence for a long period.

NEWS

MUIR-TORRE SYNDROME

First described by Muir et al in 1967 and Torre in 1968, Muir-Torre syndrome (MTS) is a rare autosomal dominant genodermatosis characterized by at least one sebaceous gland neoplasm and at least one visceral malignancy. Muir-Torre syndrome follows an autosomal-dominant pattern of inheritance in most cases with high penetrance and variable expression, but sporadic cases have also been reported. Because MTS is associated with germline mutations in the DNA mismatch repair (MMR) genes hMSH2 and hMLH1, it is considered a phenotypic subtype of Lynch syndrome (also known as hereditary nonpolyposis colorectal cancer syndrome), in which inherited defects in DNA MMR genes result in microsatellite instability. Although germline disruption of hMLH1 and hMSH2 is evenly distributed in Lynch syndrome, more than 90% of MTS patients show hMSH2 disruption. Although MTS is rare, pathologists have an important role in the early detection and initial diagnosis of MTS: identification of at-risk individuals (affected patients and family members) allows appropriate screening and surveillance for visceral malignancies, thereby reducing morbidity and mortality (Bhaijee F, Brown AS. Muir-Torre Syndrome. *Arch Pathol Lab Med*. 2014; 138: 1685–1689).

MEASLES: MANIFESTATIONS AT THE STAGE OF ELIMINATION OF INFECTION AND DIRECTIONS FOR EFFECTIVE MANAGEMENT OF THE EPIDEMIC PROCESS (Abstract): Controlling measles is still important despite the significant progress achieved through routine immunization. **Aim:** to identify the weak points of the infection control system and to determine the directions for effective management of the epidemic process using the example of the local epidemic situation. **Material and methods:** The materials for the study were data from the official registration of the incidence of measles among residents of a large industrial city in 1988-2016 and the results of serological screening for anti-measles IgG of health care workers during the outbreak of measles in 2016. The epidemiological, clinical, serological and statistical research methods have been used. **Results:** In conditions of a high level of vaccination against measles in the metropolitan population, significant quantitative and qualitative changes occurred in the epidemic process of this infection. Between 2001 and 2015, on the territory of the city, local cases of measles were not recorded, and its single penetration from endemic territories did not cause the spread of the infection. However, in 2016, a measles outbreak was registered, due to the spread of infection mainly in medical settings among patients and staff. Serological immunity tests for measles conducted among health care workers showed that up to 80% of those who underwent the tests had a protective level of anti-measles antibodies, with the highest proportion of people with seroprotection being detected in the age group over 50 years old. Up to 40% of workers with an interval of 10 years and more after the last vaccination were included in the cohort of persons with anti-measles IgG below 0.18 IU / ml, i.e. below protective level. **Conclusions:** Measles remains an important infection, which has a possibility to spread among children and adults who are not protected against it. To effectively control the epidemic situation for measles during the elimination stage of the infection, it is necessary to implement a system of continuous monitoring of the intensity of measles immunity in the indicator groups and to perform routine immunization against measles once every 10 years up to 50 years of age. In the outbreaks where the first patient was not previously vaccinated, it is necessary to carry out booster immunization with live measles vaccine for contact people without preliminary screening. **Keywords:** MEASLES, EPIDEMIC PROCESS, CONTROL.

Until the middle of the 20th century, the importance of measles was universally determined by the high incidence rate among young children, the ubiquitous spread of infection and high mortality (1, 2).

The introduction of live measles vaccine into the health care practice in 1967 made it possible to significantly change the situation: morbidity and mortality rate from this infection decreased, and the age distribution of the sufferers and the focality changed (3, 4).

Due to the constantly increasing coverage of the population with vaccinations, at the end of the 20th century and the beginning of the 21st century there was a pronounced tendency to reduce morbidity in most countries of the world and even to stop the circulation of the virus in separate time intervals (5, 6, 7).

However, since 2013, in many countries, the incidence of measles has been observed with the active involvement of adolescents and adults in the epidemic process, the emergence of measles outbreaks in community and the focality. Cases of measles were reported even in countries where measles had not occurred for a long time (USA, Canada, Australia and most European countries) (8, 9, 10, 11, 12, 13).

In several administrative territories of the Russian Federation, the cases of measles penetration and its spread with the formation of epidemic foci in families, medical settings and educational institutions began to be reported (14, 15).

The aim of the study is to identify the weak points of the infection control system and to determine the directions for effective management of the epidemic process using the example of the local epidemic situation.

MATERIAL AND METHODS

The study was conducted in 2016-2017 at the Department of Epidemiology of Ural State Medical University. The materials for the study were data from the official registration of the incidence of measles in a large industrial city for the period from 1988 to 2016: forms of federal state statistical surveillance № 1, 2; materials of the state report "On the state of sanitary and epidemiological welfare of the population in the Sverdlovsk region"; expedited reports, form 058 / y (1218).

To determine the main characteristics of the measles epidemic process, a more detailed analysis of the local epidemic situation which was formed in the megalopolis in 2016 was carried out. The analysis was based on reports on epidemic emergency situations (83), cards of epidemiological investigations of measles cases or suspected cases of this infection (72) and medical records of inpatients, form 003 / y (74).

Additionally, the results of serological tests for anti-measles IgG of health care workers were analyzed (369). Serological tests were performed at the accredited laboratories using the method of enzyme immunoassay (ELISA). The concentration of anti-measles antibodies of IgG class below 0.12 IU / ml was considered as the negative result of ELISA, 0.12-0.17 IU / ml was considered as doubtful and more than or equal to 0.18 IU / ml was positive. The analysis of the results was carried out considering age, position and vaccination history.

The epidemiological, clinical, serological and statistical research methods have been used. The study was retrospective. Generally accepted statistical techniques were used to assess the results obtained. The study of the trend of long-term morbidity pattern was carried out using the standardized range (estimated Hurst exponent) and the average growth / decline rate in morbidity. To evaluate the activity of epidemic foci of measles,

the indicators such as the index and the factor of focality, as well as the indicators of infection reproduction (reproductive indices) were calculated.

The calculations were made using the Microsoft Office 2007 application package. The statistical significance was assessed using the Student's test and the Fisher test. Differences were considered significant at $p < 0.05$.

RESULTS

With the high coverage of measles vaccinations in the city inhabitants of 95.0-97.0%, there have been significant changes in the epidemic process of this infection. Between 1988 and 2001 a steady downward trend in morbidity was reported in the city. The estimated Hurst exponent for the period studied was 0.6, which also allowed to determine the multi-year dynamics in measles as trend resistant, with an average decline rate of 10.87 per cent.

Between 2001 and 2015, on the territory of the city, local cases of measles were not recorded, and its single penetration from endemic territories did not cause the spread of the infection. The situation changed at the end of 2016 when the measles outbreak was recorded in the city. 72 clinically and laboratory confirmed cases of measles were identified within 11 weeks.

In the laboratory test using ELISA method, specific M antibodies were detected in all sufferers. In the PCR study, the antigen of the measles virus of genotype D8 was isolated, which circulated in previous seasons in the countries of South-East Asia, and in 2015 season it circulated in Europe and Russia.

In the age structure of the sufferers, children and adolescents up to the age of 18 (68.1%) predominated, and adults accounted for 31.9%.

The average age of the sick children was 3.8 years. Children of younger age groups, namely, up to 2 years old and 3-6 years old (46.9% and 40.9%, respectively) were mainly involved in the epidemic process, whereas children over 7 years old made up only 12.2%.

In adults, the average age was 33.2 years, and the greatest number of cases fell on the age group of 20-29 years (39.1%) and 30-39 years (30.4%). The proportion of people aged 18-19 was 4.4%, and over 40 years was 26.1%. There were no differences in the gender structure of measles cases.

According to the vaccination history, 68.1% of the cases had not previously been vaccinated against measles, including because of the refusal of vaccination (38.8%), medical exemption (34.7%), and age (16.3%). In 10.2% the reasons for the lack of vaccination were not documented. Among the measles sufferers, who were previously vaccinated, 30.4% were vaccinated once, 47.9% were vaccinated twice and 21.7% were vaccinated three times.

It should be noted that those who got measles among the previously vaccinated persons did not become active sources of infection for those who contacted them. The incidence rate in persons who contacted them was 0.53 ± 0.15, whereas in foci in contact with previously unvaccinated sufferers it was 7.94 ± 0.56 ($t = 12.78$, $p < 0.05$).

According to clinical manifestations, in 90.3% of cases the typical measles is described with the presence of all classical symptoms and the stage of their appearance. Among the sufferers who were not previously immunized, typical manifestations of measles were observed in 98.1%, and they were observed among vaccinated sufferers only in 70%.

The change the rash (macular and roseoseous), the lack of staging of its appear-

ance and pigmentation were reported in atypical forms of measles, in the previously vaccinated sufferers. In the unvaccinated sufferers, the atypical forms of measles were characterized by the absence of symptoms of intoxication and unmarked catarrhal manifestations.

It should be noted that the clinical manifestations of measles in previously unvaccinated patients were more pronounced: hyperemia of the throat, rhinitis, cough and fever up to febrile figures were reported more often.

During the outbreak, 59 local foci were formed with a different number of sufferers, including 36 family-home, 14 in organized communities and 9 in medical settings. In 30.6% of family-home foci there was a spread of infection, including 8 - within the same apartment, in one - in the block and in two foci - both in the apartment and in the block to the higher floors. The index of focality in family-home foci was 1.33, the factor of focality was 30.6%, and the infection reproduction index was 1.1.

In 14 organized communities were involved in the epidemic process, including 7 preschool educational institutions, 5 schools and 2 higher educational institutions, including one with the spread of infection among students (3 people). The index of focality in organized communities was 1.14, the focal factor was 7.1%, the infection reproduction index was 3.0.

The most active spread of the infection occurred in medical settings, where the index of focality was 7.1, the factor of focality was 55.6 per cent, and the infection reproduction index reached 10.2.

DISCUSSION

Five multidisciplinary city hospitals, one of the departments of the children's anti-tuberculosis center, an ambulance station, a private clinic and a medical and sanitary unit at the university were involved in the epidemic process. There was a spread of the infection in more than half of the hospitals. The total number of subsequent cases of measles was 51.

The spread of infection in the medical settings was due to the presence of children and adults who were not previously vaccinated against measles, late diagnosis of measles in the first and subsequent cases, and violations in the organization of anti-epidemic measures.

When analyzing the results of a serological test of the health care workers for anti-measles IgG, it was found that 79% of workers had sufficient seroprotection level.

In the 18-19 age group, the proportion of persons with and without seroprotection was approximately equal. However, for individual age groups, the proportion of persons with seroprotective antibody levels at the age over 50 was the largest and constituted 90.5% (fig. 1).

Among the different categories of health care workers, there were no significant differences in the proportion of persons with seroprotection (tab. I).

Considering the vaccination history, among those who were vaccinated once, the proportion of people with seroprotection was 82%, among those who were vaccinated twice and three times it was 76.6% and 77.8%, respectively. Among those who had had measles earlier, all examined persons showed a sufficient level of seroprotection, and in persons with a lack of data on measles vaccination the positive results in ELISA were about 80%

It should be noted that with an increase in the number of years elapsed since the date of the last application of the vaccine, the proportion of persons without seroprotection increased from 17 to 40% (fig. 2).

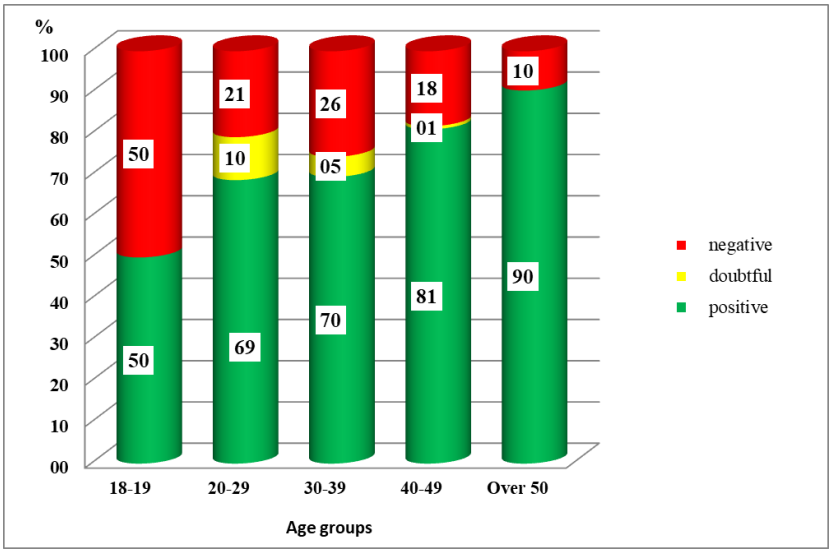

Fig. 1. Results of serological tests for anti-measles IgG in health-care workers in the selected age groups

TABLE I

Levels of protective concentrations of anti-measles IgG among health care workers

Position	Result of the study						Total	
	positive		doubtful		negative			
	No.	%	No.	%	No.	%	No.	%
Doctors	81	77.1	4	3.8	20	19.0	105	100.0
Nursing staff	98	78.4	6	4.8	21	16.8	125	100.0
Paramedical staff	42	85.7	0	0.0	7	14.3	49	100.0
Administrative staff	72	80.0	0	0.0	18	20.0	90	100.0

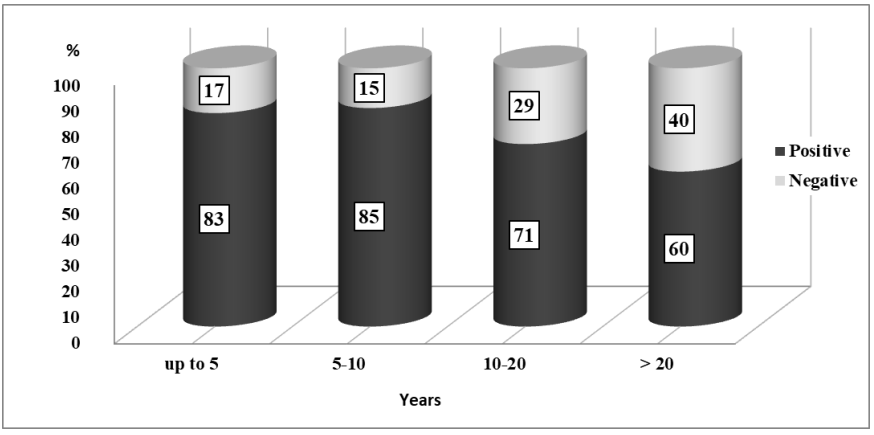

Fig. 2. Proportion of persons with seroprotection and interval from vaccination against measles

CONCLUSIONS

1. Despite positive changes towards the elimination of measles, it remains an important infection which can spread among children and adults who are not protected against measles.

2. The significance of measles cases in previously vaccinated sufferers as potential sources of infection in the foci is low, the spread of the infection upon exposure to them was 0.53 ± 0.15, whereas it was 7.94 ± 0, 56 in contact with those who were not vaccinated and got measles.

3. A peculiarity of the outbreak of measles was its active spread in medical settings with the formation of secondary foci along the routes of sick children and adults.

4. According to the results of serological monitoring, it was established that up to 80% of health care workers had a protective level of specific antibodies, and the greatest number of persons with seroprotection was found in the age group over 50 years. In 30-40% of workers who do not have a protective level of antibodies, the interval from the last vaccination was more than 10 years.

To optimize the system of epidemiological surveillance of measles, it is necessary to:

- Carry out scheduled revaccination against measles at intervals of 10 years up to 50 years of age.
- Carry out booster immunization with live measles vaccine to the contact persons as soon as possible without prior screening as an infection control measure in the foci where the first sufferer was not vaccinated against measles.
- Implement a system for the continuous monitoring of the intensity of measles immunity in the indicator groups recommended for screening by WHO.

NEWS

NEW DATA FOR TUBERCULOUS MENINGITIS IN HIV-POSITIVE PATIENTS

Tuberculous meningitis (TBM) ranks second in frequency in Africa, with a mortality of over 50% due to diagnostic difficulties. A recent study by Bahr et al. evaluated the diagnostic performance of the new Xpert MTB/RIF Ultra (Xpert Ultra) for TBM in the cerebrospinal fluid (CSF), comparing the Xpert MTB/RIF (Xpert) results with the results of cultures. The study group included 221 HIV-positive patients suspected of meningitis (headache, nuchal rigidity, altered mental status), of which 129 suspected of TBM were tested with Xpert, Xpert Ultra and culture. The results confirmed the diagnosis of TBM in 22 subjects (17%). Of the 21 cases positive by Xpert Ultra, 13 were positive by culture, Xpert or both, and 8 were only positive by Xpert Ultra. The study showed that Xpert Ultra had a 95% sensitivity for TBM, while the sensitivity of culture and Xpert was 45%. By using Xpert Ultra rifampicin resistance was undetected in 13 cases and undetermined in 9. In conclusion, this research demonstrated that Xpert Ultra detected more cases of MTB. The limitation of this paper is that the results cannot be extrapolated to the general HIV-negative population, as the study group consisted of a relatively small number of HIV-positive patients (Bahr NC, Nuwagira E, Evans EE et al. Diagnostic accuracy of Xpert MTB / RIF Ultra for tuberculous meningitis in HIV-infected adults: a prospective cohort study. *Lancet Infect Dis* 2017 Sept. 14 doi: 10.1016 / S1473-3099 (17) 30474-30477).

SURGICAL TECHNIQUES IN THE TREATMENT OF MULTILEVEL PERIPHERAL ARTERIAL OCCLUSIVE DISEASE (Abstract): **Aim** of the study was to report the surgical techniques for multilevel arterial lesions of the lower extremities and to evaluate the clinical outcomes. In patients with multilevel arterial disease, the treatment consisting of sequentially surgical intervention on the same vascular axis is one of the methods indicated in order to obtain an adequate inflow and outflow. **Material and methods**: we have performed a non-randomized study during a 44-month period (January 2010 – September 2013) in a number of 58 patients treated by classical revascularization techniques. All the patients included in the study have been post-surgically surveyed at well-established intervals (1, 3, 6, 9, 12, 24 and 36 months) by: clinical examination, laboratory tests, Duplex ultrasound, and, as needed, CT Angiography. **Results**: the 6 months primary patency in each studied group (corresponding to the years of 2010, 2011 and 2012) was 95%, 93.33%, and 91.3%, respectively; the 12 months primary patency was 85%, 80%, and 82.6%, respectively. Clinical improvement has been noticed in 44 patients (75.86%). There have been registered 14 amputations (24.13% of the cases): 7 majors (thigh and below the knee), representing 12.06% of the total number of cases and 7 minors (toe or transmetatarsal), representing 12.06% of the total number of cases. Limb salvage rate for the patients in stage III and IV Leriche-Fontaine was 85.10%. **Conclusions**: the surgical techniques are a feasible option for the multilevel arterial disease, with favorable patency and limb salvage rates. **Keywords**: MULTILEVEL ARTERIAL DISEASE, SURGICAL REVASCULARIZATION.

Multilevel involvement is typically observed in critical limb ischemia. Surgical interventions are a well-accepted strategy for revascularization in patients with critical limb ischemia due to multilevel arterial occlusive disease (1). A staged approach to multilevel arterial disease was the standard for numerous years, consisting of revascularization of the aorta or iliac artery followed by interval infra inguinal surgery. This approach was a rational strategy at a time when open surgical techniques were only performed in separate settings. Usually, the procedures are performed successively, although individual patient anatomy plays a part in the decision of whether to perform the two procedures simultaneously or not. The aim of the treatment is to obtain an improvement of both the inflow and the outflow.

The optimum treatment of multilevel arterial occlusive disease is often difficult to establish. There is often the need to decide if or when a concomitant or successive outflow procedure must accompany an inflow procedure. The most important decision factor is probably the severity of the distal ischemia. Both an outflow and an inflow procedure are necessary whenever there are large areas of tissue loss associated with the occlusive disease (2, 3).

MATERIAL AND METHODS

We have performed a non-randomized study in one center. The data was gathered retrospectively for a 20-month period (January 2010 – September 2011), and prospectively for a 24-month period (September 2011 – September 2013) for a number of 58 patients treated by surgical revascularization techniques at the Vascular Surgery Clinic, "St. Spiridon" Hospital, Iaşi, Romania.

The including criteria for the patients were: aged 18 and over, multilevel peripheral arterial disease in any of the Leriche-Fontaine stages, with uni- or bilateral pathology, and had an indication of revascularization by open technique (bypass or endarterectomy, with or without angioplasty). The study included 58 patients (female 3.4%, male 96.6%, mean age 62.6 years).

The patients were divided into two groups: 1 – included patients who had the surgical techniques done in one procedure; 2 – included patients treated in two successive procedures.

Peripheral arterial disease was localized at a minimum of two levels on the same vascular axis: aortic, iliac, and inguinal (involving the common, deep femoral artery and the origin of the superficial femoral artery), or infra inguinal (supra- or infra genicular).

All patients were pre-operatively evaluated by physical examination, blood tests, Duplex scan, angiography or CT angiography. Also, the risk factors and associated co morbidities were noted.

Postoperative surveillance at well established time intervals (1, 3, 6, 9, 12, 24 and 36 months), consisted of: blood tests and Duplex scans, clinical examination (improvement of the claudication distance, amelioration of rest pain, healing of trophic lesions). We evaluated the primary and secondary patency of all procedures, initial technical success, complication rate, morbidity and mortality associated with each technique, amputation-free survival rate, symptomatic improvement, and the risk factors that influenced the postoperative outcome and recovery period.

The statistic analyses were performed in *SPSS, version 15.0* (SPSS Inc., Chicago, IL, USA). A p value of less than 0.005 was considered statistically significant. During the study, the primary and secondary patients were analyzed using the Kaplan-Meier estimator.

RESULTS

For the 58 patients included in the study, the open techniques consisted of an autologous or synthetic bypass graft and/or femoral endarterectomy. Twenty-five patients had concomitant revascularization procedures, and 33 had successive procedures (fig. 1).

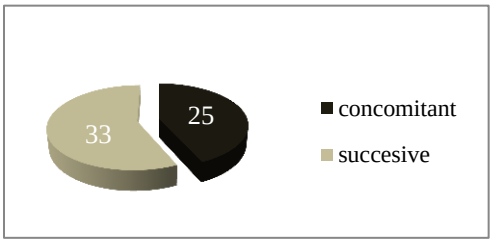

Fig. 1. The distribution of cases according to the sequence of revascularization procedures

Most patients in the given cohort were in the fourth stage of disease (53.4%). Although we observed a better primary patency for this subgroup of patient, compared with those in the second and third disease stages, the difference wasn't statistically significant. Inflow procedures followed by outflow procedures were the most often used ones, most of them being successive (58.69%), rather than simultaneous (fig. 2).

Synthetic grafts were used for most inflow procedures, whereas autologous material was the main choice for outflow procedures.

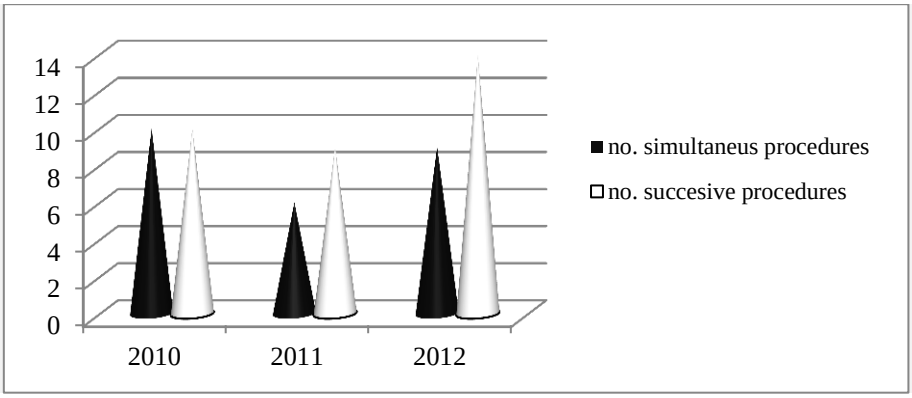

Fig. 2. Yearly distribution of multilevel occlusive disease surgical repairs

For the studied period of time, we constructed infra inguinal extension grafts for 27 aortobifemoral, 4 aortofemoral, one axilobifemoral and 19 iliofemoral bypasses. Three femoropopliteal bypasses required extension grafts and four common femoral artery endarterectomies required a redo with femoropopliteal bypasses.

The study included 13 graft thrombectomies using Fogarty catheters, 20 proximal anastomosis patch angioplasties and 6 vein Miller cuff angioplasties for distal anastomoses.

Elective procedures were performed for 77.58% of the patients and emergency procedures for the rest of 22.41% of the patients, with acute or subacute ischemia. The emergency procedures consisted of graft thrombectomies with or without simultaneous extension grafts. The initial technical success for all procedures was 100%.

We had no early artery or bypass occlusions (less than 30 days) and only one case with a postoperative local hematoma which required a reintervention for haemostasis and evacuation.

We had two graft infections (one case required an additional myoplasty, with favorable postoperative recovery at two years, and the other case required extraction of the infected synthetic graft and construction of a new bypass using the great saphenous veins).

We registered 13 late occlusions (after more than 30 days), which entailed follow-up procedures for reestablishing the patency.

There were 14 (24.13%) amputations recorded: 7 majors (thigh or below-knee), representing a rate of 12.06% of the total number of cases and 7 minors (toe or trans metatarsal), representing a rate of 12.06% of all cases. Limb salvage rate for the patients in stage III and IV Leriche-Fontaine was 85.10%. The amputation-free survival

period ranged between 1 and 36 months, with an average of 16.33 months. Clinical improvements were noticed in 44 (75.86%) patients. The mortality rate for the entire studied period was 5%.

After six months primary patency in each studied group (corresponding to the years of 2010, 2011, and 2012) was 95%, 93.3%, and 92.3% respectively, comparable with those published in the literature (Shilagy). After twelve months primary patency was 85% in the 2010 studied group, 80% in the 2011 group of patients, and 82.6% for the 2012 group (fig. 3, 4, 5).

We did not find statistically significant differences between the averages of the primary patients of various disease stages. Most of the patients who benefited from simultaneous revascularization procedures were in Leriche IV disease stage.

As far as the connection between the type of revascularization procedure and the primary patency is concerned, the average primary patency for the successive procedures is the same as the one for simultaneous procedures. The primary patency did not differ between the elective and emergency procedures subgroups.

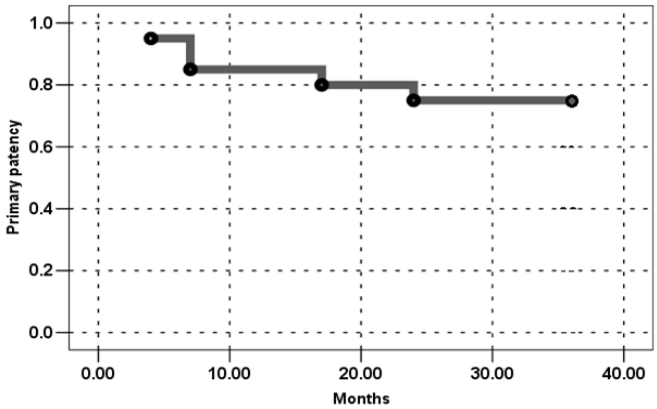

Fig. 3. The Kaplan-Meyer diagram of primary patency for the 2010 patient group

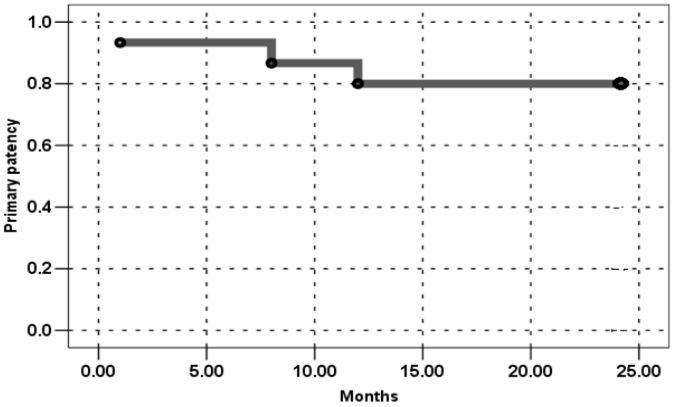

Fig. 4. The Kaplan-Meyer diagram of primary patency for the 2011 patient group

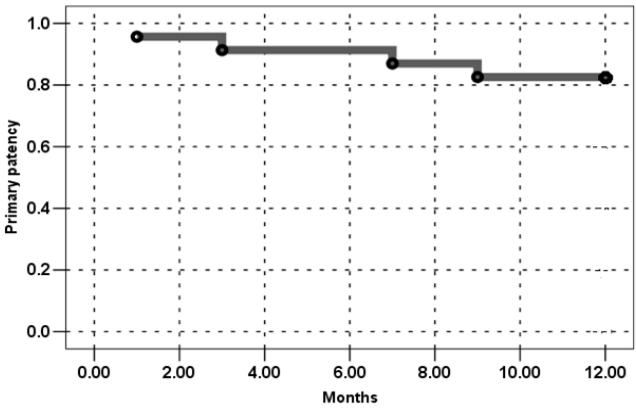

Fig. 5. The Kaplan-Meyer diagram of primary patency for the 2012 patient group

The difference in primary patency between the patients who benefited from synthetic grafts revascularizations and the ones with autologous material is statistically non-significant.

The statistical analysis identified the only risk factor which significantly influenced the primary patency in the studied group: *arterial hypertension*.

DISCUSSION

Critical ischemia due to multi-level arterial occlusive disease may necessitate both an inflow procedure and an outflow procedure, if limb salvage is to be accomplished. Direct surgical repair is the optimum choice for fit patients with a life expectancy of more than two years (4).

Simultaneous multi-level revascularization is a safe and efficient procedure for critical ischemia (5).

In a 15 years retrospective study published in 2014, Sharples and co. report on a single center experience with the treatment of multi-level occlusive disease using simultaneous aortoiliac and infrainquinal bypasses done between 1996 and 2011. Limb salvage rate was 96.9%, 85.7% and 75.9% at 30 days, one year and 5 years respectively. These results demonstrate that multi-level bypasses can be constructed with good long term results. For patients with critical ischemia and tissue loss due to both aortoiliac and infrainquinal occlusive disease, significant benefits exist if an initial multi-level revascularization procedure is accomplished (6).

Following their study on 121 patients (with 201 revascularized limbs) Horstmann and co. have concluded that combined aortofemoral and profound femoral artery reconstruction was desirable in treating multi-level occlusive disease and that infrainquina*l* extension grafts were needed only for critical ischemia (7).

Dalman and co. reported on a study of 62 patients that multi-level procedures offered a complete resolution of symptoms for a greater percentage of patients than single level procedures did (8).

Edwards et al agrees that multi-level aortoiliac and femoral occlusive disease necessitates profound femoral artery angioplasty or an outflow extension graft in order to secure pelvic and distal arterial perfusion (9).

For our surgical cases, the profound femoral artery (PFA) had the most important role. This was the distal anastomosis site for the inflow procedures, with or

without venous or arterial patch angioplasty in the case of 14 patients. Constructing an angioplasty enhanced anastomosis on the PFA for aortobifemoral bypasses yields superior early and long term patency, compared to a distal anastomosis on the common femoral artery (10). The profound femoral artery angioplasty proves very useful when the superficial femoral artery is thrombosed. We observed significant benefits throughout the study from utilizing it adequately. Using for distal anastomosis venous or arterial cuffs on the profound femoral artery decreases the rate of infrainquinal extension grafts. We used simultaneous extension grafts for patients with tissue loss (Leriche IV disease stage) and critical ischemia due to type III aortoiliac disease.

In order to achieve secondary patency, graft repermeabilization was achieved with Fogarty catheters and extension grafts were constructed with distal anastomosis on the profound femoral artery or more distally. These procedures require extensive surgical experience. Adequate surgical exposure and use of the profound femoral artery is the key for aortoiliac disease surgical reinterventions (11).

CONCLUSIONS

In our study simultaneous or successive surgical procedures are a feasible option for multilevel peripheral arterial occlusive disease, with favorable patency and limb salvage rates. The observations of the current study indicate that the profound femoral artery plays an important role in conventional surgery.

LONG TERM BIOLOGICAL EFFECTS INDUCED BY IONIZING RADIATION – IMPLICATIONS FOR DOSE MEDIATED RISK

LONG TERM BIOLOGICAL EFFECTS INDUCED BY IONIZING RADIATION – IMPLICATIONS FOR DOSE MEDIATED RISK (Abstract): Ionizing radiations are considered to be risk agents that are responsible for the effects on interaction with living matter. The occurring biological effects are due to various factors such as: dose, type of radiation, exposure time, type of biological tissue, health condition and the age of the person exposed. The mechanisms involved in the direct modifications of nuclear DNA and mitochondrial DNA are reviewed. Classical target theory of energy deposition in the nucleus that causes DNA damages, in particular DNA double-strand breaks and that explanation of the biological consequences of ionizing radiation exposure is a paradigm in radiobiology. Recent experimental evidences have demonstrated the existence of a molecular mechanism that explains the non-targeted effects of ionizing radiation exposure. Among these novel data, genomic instability and a variety of bystander effects are discussed here. Those bystander effects of ionizing radiation are fulfilled by cellular communication systems that give rise to non-targeted effects in the neighboring non irradiated cells. This paper provides also a commentary on the synergistic effects induced by the co-exposures to ionizing radiation and various physical agents such as electromagnetic fields and the co-exposures to ionizing radiation and chemical environmental contaminants such as metals. The biological effects of multiple stressors on genomic instability and bystander effects are also discussed. Moreover, a brief presentation of the methods used to characterize cyto- and genotoxic damages is offered. **Keywords:** IONIZING RADIATION, GENOMIC INSTABILITY, BYSTANDER EFFECTS, STOCHASTIC EFFECTS, SYNERGISTIC EFFECTS.

The linking bridge between ionizing radiation and risk (expressed in various signs, symptoms and illness) has existed since the early age of X-ray discovery by Röntgen. In less than a year (1896) skin burns produced by X-rays exposure have been reported by Stevens (1) and Gilchrist (2) and the first radiation induced skin cancer has been reported 7 years later by Frieben (3).

Our body is daily bombarded by energetic quanta of various origins and energies. From the secondary cosmic particles and nuclei, radio waves, infrared and ultraviolet light we are the subjects of a permanent intake of energy by collisions. All the energy supplied by these quanta is accumulated in our cells, tissues and organs. Of course, not all of them are fulfilling the required

threshold for producing biological effects, but it is possible that they are involved in a *tunneling effect* whose final result is the caption and deposit of the transferring energy inside our body, through elastic and inelastic (non-elastic) collisions. Each and every radiation energy carrier won't produce deterministic effects, but they are preparing and facilitating the action of future bombardments energy quanta, which, in this case, (why not?) will produce effects responsible for triggering of illness starters.

BIOLOGICAL EFFECTS OF IONIZING RADIATION (IR)

Two types of biological effects have been observed: deterministic effects that occur in the early stages of irradiation (few hours to few days) for high (5-15 Gy) and very high doses (above 15 Gy), and stochastic effects (which appear 4 to 10 years after irradiation) and they are in connection with low doses (0.05 – 0.5 Gy).

Naturally, the mean energy received by each of us is approximately 2.5 mSv per year, from γ-rays action only (4). The energy exposure to other types of radiations is variable for each individual and yet unknown, due to its difficulty to be measured. What we know for sure is that a higher absorbed dose will increase the risk of potential cellular injury. There have been described several dose modifying factors: the type of radiation (α-particles and other nuclear particles - like neutrons - perform a higher ionizing power and they are more damaging hazards than the less densely ionizing radiation, such as X-rays and γ-rays), the intensity of those radiations (the risk to develop DNA damages rises with the increase of the radiation intensity), the exposure time (energy transferred on a short period of time has a greater potential for DNA damage), the part of our body which has been irradiated (the gonads, blood-forming organs and the lens of the eye are much more sensitive to radiation damage) and, of course, the age of the exposed person (children are more sensitive to radiation effects than the adults are) (5).

More than the above mentioned dose (2.5 mSv/year), for diagnostic purposes, patients are irradiated either from outside of the human body (that happens when methods using X-rays are involved – radiography and CT-scan – or γ-rays are involved like in radiotherapy) or from the inside of the human body like γ-rays used in scintigraphy. These procedures, performed once or, some time, more than once a year, add an extra statistically calculated mean of 1 mSv for each of us every year (4). If you want to have a quantitative representation of the dose received during an imagistic method like PET-CT, notice that a 250 MBq injection of ^{18}F-fluorodeoxyglucose which is normally administered to the patients leads to an effective dose of 5.8 mSv (equal to the dose that would be received in 1.7 years from nature!) (5). This amount of radiation is considered to be a low dose in the classification of doses made by ICRP (International Commission on Radiological Protection) (6). Nevertheless, those small doses (and perfectly legal) implies supplementary processes of radiation exposure which will always involve stochastic mechanisms.

Concerning of human risk at low doses of ionizing radiation (mainly X and gamma) has been expressed by various authors in past decades. In a review (7), Kam and Banati showed that due to a citation analysis of published literature performed on 22 May 2013 through Web of Science/ Thomas Reuters, from 2003 to 2013 decade more

than 120 articles have been published each year in respect of implications for low doses. This shows the immense interest for the theme of the possible and probable effects of ionizing radiation that covers a wide area of mechanisms that include (without being limited to) non DNA targeted effects (NTEs) with genomic instability (GI) as a part of it, and a variety of bystander effects (BE) with abscopal effects and bystander mediated adaptive response as the principle mechanisms (8).

CHEMICAL EFFECTS OF IONIZING RADIATION

Exposure of living cells to ionizing radiations initiate direct and indirect cellular effects on macromolecules. The direct mechanisms imply the breaking of the atomic structures producing chemical and biological changes. Indirect effects imply both excitations and ionizations leading to the radiolysis of cellular water with a resulting plethora of free radicals. The free radicals can initiate modifications on other critical molecules (indirect effect). By stimulation of oxidases and nitric oxide synthases they will generate a major source of ROS/RNS in irradiated cells under ambient oxygen. The indirect cellular effects of ionizing radiation cause lipid peroxidation, protein oxidation, oxidative alterations to nuclear DNA (nDNA) and mitochondrial DNA (mtDNA) and inactivation of enzymes (9).

TARGET THEORY

In the target theory, in order to produce effects the ionizing radiation must hit a critical site. It is unanimously accepted that nuclear DNA is the critical target for radiation in determining cell death as well as non death-related effects. Recently, scientists have proven that the target theory must be taken into consideration when referring to the mitochondrial DNA (8).

NON-TARGETED EFFECTS

According to Khadim et al. non-targeted effects (NTEs) are those processes that occur in the non-irradiated cells and had received signals from a cell previously irradiated (8). NTEs are not observed in all experimental models and variability characterizes the genotoxic stress responses (10). As mentioned above, NTEs include bystander effects, genomic instability and abscopal effects.

Radiation induced bystander effects (RIBE) have been observed in non-irradiated cells but which previously existed in the same physical environment with the irradiated cells (11). RIBE was also observed in the cells that were placed in a medium that has been transferred from cell cultures that have been previously irradiated (12). Moreover, W.F. Morgan has observed RIBE in both *in vitro* cell culture (13) and *in vivo* model systems (14).

Radiation induced genomic instability (RIGI) represents the radiation effects that were observed in the non irradiated progeny that are clonally descended from an irradiated cell (15).

Abscopal effects or distant out-of-field mechanism is a bystander effect associated with radiation therapy (16). During oncologic radiotherapy the tumor is irradiated with a dose of about 60-70 Gy, which represents a very high dose according to M. Khadim (8) and the healthy normal tissue in the field of the γ-rays beam receives a lower radiation dose for about 4-6 Gy (17). The abscopal effects are generated by the radiation from the environment of the patient, from the device contribution and from the internal scatter (18). Abscopal

effects must be considered low dose radiation effects and therefore not NTEs mechanism. In fact, abscopal effects are contributing to stochastic effects.

STOCHASTIC EFFECTS

The amount of radiation used in medical diagnosis (with γ-rays and X-rays) are well below what is it known to produce "radiation sickness". But those low doses are of peculiar interest for the long term effects. The most important of these stochastic effects are: i) genetic damage of the cell (mutagenesis), ii) damage of the chromosomes (clastogenesis) and iii) carcinogenesis.

Until now, there is not a complete understanding of the relationship between exposure to low dose of radiation and the resulting effects consecutive to its action. The regulations and guidelines currently used in nuclear medicine laboratories all over the world are mainly based on a *linear nonthreshold* (LNT) model. This model states that there is "no threshold dose" for long term effects and the risk of an exposed person (patient or nuclear medicine laboratory personnel) increases linearly with radiation dose.

Unfortunately, in opposition with that model there are facts, reliable experiments, scientific data that had led to different radiation injury models that are inconsistent with the LNT model. There are consistent studies that emphasize that low doses of radiation have a beneficial effect on health, resulting from the stimulation of the immune system (19, 20).

BIOLOGICAL DOSIMETRY

Due to the fact that exposure to ionizing radiation causes chromosome rearrangements and, it was well established, that high doses of ionizing radiation are carcinogenic (21), a method was needed to characterize the molecular transformations. To emphasize the exposure to ionizing radiation, the method of chromosome aberrations as a biological marker has been widely accepted. This method also known as FISH (fluorescence *in situ* hybridization) has the capability to identify and quantify chromosome damages determined by the exposure to IR. In a particular way, this method is important because it can express detectable levels of translocation in medical exposures at low doses of radiation long after the cell has been irradiated. It can detect the resulting transformation month or even years after the exposure episode happened (21).

Other tests used to characterize the changes in number and structure of chromosomes and genetic mutations are sister chromatid exchange (SCE) that involves DNA breakage and reunion (22), and micronucleus method (MN) that evaluates numerical and structural chromosome damages (23).

SYNERGISTIC EFFECTS

Another important aspect regards the exposure of ionizing radiation at environmentally and/or therapeutically relevant doses together with a co-exposure to other physical and chemical agents. Very few things are known in the respect of the cumulative effects of non-ionizing electromagnetic fields on short or long term action, combined with ionizing radiation exposure (24). Even so there are controversial reports on the co-exposure to physical stressors. Early studies have focused on the usage on a large scale of the electromagnetic fields based methods in curative medicine and for diagnostic purposes. Thus, in an experiment conducted by Geard et al.

(25) on the effects of the exposure of magnetic resonance on mouse C3H 10T1/2 cells, there was not recorded an ionizing radiation – like effectiveness for cell killing, transformation and chromosome aberrations. Several other *in vitro* studies using extremely low-frequency electromagnetic fields from 0.7 to 400 mT for different periods of time, combined with a single dose exposure to X-rays or γ-rays (between 3 to 12 Gy) figured out controversial results (26). Lagroye and Poncy reported a significant enhancement of genomic damage by an increased formation of micronuclei (MN) in normal cells from rat tracheal epithelium (27). Jian et al. have been reported an induced apoptosis in a hepatoma cell line due to an increase of aneuploidy (28), while Mairs et al. recorded an increase of the mutations rate induced by ionizing radiation, even at very low doses (29). On the other hand, some authors have reported no detectable changes due to exposures to both ionizing radiation and extremely low frequency magnetic field in a human amniotic fluid cell line (30), breast cancer cells (31), or rodent repair-proficient cells (32).

Moreover, there is a lack of conclusive data regarding the biological effects of co-exposure to chemical contaminants and ionizing radiation. Acute contamination with chemical agents is very rare (except drugs cancer therapy). So, of particular interest is the case of chronic exposure to chemical agents combined with ionizing radiation exposure. There are works that show an increase of genomic instability due to chemical agents (33) while in the estimation of cancer risk Preston notified that the non-targeted effects (NTEs) have been enhanced by co-exposure to chemicals and radiation (34). As a result of the numerous works on that field of interest, an official organization UNSCEAR (United Nations Scientific Committee on the Effects of Atomic Radiation) recognized that in biological systems ionizing radiation is the main physical genotoxic and carcinogenic agent to which we all are exposed and also that low levels of chemical genotoxins such as UV-mimetic agent 4-nitroquinoline 1-oxide (4-NQO) and the metalloid arsenic (As), one of the most widespread element in drinking water, could generate a multiplicative or synergistic effect if an environmental and/or occupational ionizing radiation exposure occurs (35). More recently, the same synergistic effect associated with genomic instability was recorded in human small airway epithelial cells by *in vitro* chronic exposure to As (36). The authors have demonstrated that the key role for mediating the response to DNA damage and for its surveillance and/or maintenance of genome stability was assured by the p53 encoded protein. Another study on a heavy metal Cr (VI) and ionizing radiation synergistic effects have proved the induction of genomic instability in human fibroblasts (37). Moreover, the synergistic modulation of water metal contaminants like cadmium and aluminum and the induced bystander effect of ionizing radiation have been demonstrated in an *in vivo* experiment on salmon (38).

CONCLUSIONS

New studies are needed in order to clarify the mechanisms of the combined exposures scenarios for short and long term cumulative effects. Cancerogenesis, genomic instability and premature cellular senescence (a non-cancer late effect) must be investigated in pluriparameter experiments in which the everyday life co-

exposures to ionizing radiation, electromagnetic fields such as microwave fields associated with mobile telephony and Wi-Fi technology and chemical contaminants in environmentally normal concentration must be taken into consideration.

SPLIT-THICKNESS SKIN GRAFTING IN ONCOLOGIC SURGERY OF THE LIMB – A CASE REPORT (Abstract): Large excision of tumor soft tissues is often complicated by infections, seriously undermined blood supply and venous drainage, tendon exposure, functional impairment. We report the case of a 67 years old woman admitted for a sarcoma of the right forearm occurring 14 years after a modified radical mastectomy and adjuvant chemotherapy for carcinoma of the right breast. A wide excision of the lesion and split-thickness skin graft was performed with uneventful recovery and satisfactory healing of the graft tissue and functional aspect of the arm. In the last few decades, there has been a search for solutions in tissue repair without need for auto grafts, such as biological substitutes that could repair or improve the function of tissue. In case none of these products are available, auto graft is a good choice and it may be commonly used in the surgical treatment of postoperative soft tissues defects after oncologic surgery. **Keywords**: SKIN GRAFT, MULTIPLE NEOPLASM, LYMPH EDEMA

Direct closure is the reconstruction of choice for surface soft tissue defects. Major causes of recipient site morbidity after skin grafting a postoperative defect of the upper limb are lack of skin graft take to complete loss, functional impairment, infection, hematoma/ seroma and paresthesia. Long-term cosmesis remains poor. In the last few decades, there has been a search for solutions in tissue repair without need for auto grafts. This has produced a development of biological substitutes that could repair or improve the function of tissue.

The use of these products enlarges the spectrum of therapeutic resources available for the treatment of skin lesions, thereby changing the approach to many diseases (1). In case none of these products are available, auto graft is a good choice and it may be commonly used in the surgical treatment of postoperative soft tissues defects after oncologic surgery.

CASE REPORT

A 67 years old woman was hospitalized in our clinic for a swelling of the right forearm that appeared 9 months ago.

She has a history of modified radical right mastectomy (Madden operation) 14 years ago for infiltrating ductal carcinoma

of the right breast- $T_2N_0M_0$; followed by 6 cures of chemotherapy and antiestrogen treatment (Tamoxifen) for 5 years; no radiotherapy was commenced. She also declares the presence of mild lymphedema of the upper limb in the last 8 years.

The patient noticed the gradual increase in size of the swelling described and complains of non-radiating, moderate burning-like pain of the area; further on she noticed the appearance of several nodules along the anterior face of the forearm that ulcerated in the last 6 weeks. An ultrasound and CT scan of the forearm performed on outpatient basis 6 months ago revealed chronic cellulite; therefore she received a topical anti-inflammatory treatment. The local physical examination when presenting in our service showed the presence of mild lymphedema of entire right arm and purpuric spots from the elbow to the wrist. On the anterior face of the forearm, a 12 × 8 cm purple area with multiple nodular lesions, tending to confluence, some of them ulcerated, with surrounding erythema and induration was noted; apparently, on clinical examination, the subcutaneous tissue of the described area was infiltrated (fig 1) We did not find any motor, vascular (peripheral arteries) or sensitivity changes from the right shoulder joint to the right fingers.

Fig. 1. Lesion aspect on admission

The actual blood tests showed no modifications, abdomino-thoracic CT scan and bone scintigraphy did not reveal any pathological modification related to the current condition or to the breast cancer from her history. PET scan and MRI scan were not available.

The anatomopathological examination on the tissue prevailed by biopsy showed conventional high-grade angiosarcoma and microscopically examination exhibited a mixture of vasoformative features, including intravascular infiltration tumoral vascular lumen, papillary projection into the lumen of the vessels; therefore, given the history, symptoms and pathology, our first diagnosis was angiosarcoma developed on upper limb lymphedema. But the

great dilemma was brought by the immuno-histochemical tests showing specific aspects of Kaposi sarcoma (positive CD_{31}, CD_{34} and HHV_8), without succeeding a final, reliable differentiation between the two forms of sarcoma. Under these circumstances, an oncologic wide excision of the lesion and free split skin graft in tied over manner was performed under general anesthesia (fig 2).

a. **b.**

Fig. 2. Excision of the cutaneous lesion (a) and aspect of the skin graft on the 5-th postoperative day (b)

The immediate postoperative recovery was uneventful with satisfactory healing of the graft tissue and functional aspect of the arm and the patient was discharged 8 days postoperatively in order to initiate oncologic treatment recommended by the oncology board. On the 3rd week postoperative the patient was one again hospitalized for a local relapse represented by the same aspect cutaneous nodules on the edge of the graft. A local re-excision was performed; even if there was a great probability that the lesion would invade the antebrachial aponeurosis, we did not excise it because of the risk of harming the radial vessels which would not bring the patient any benefit considering the disease's fulminant evolution. We used the same type of skin graft to cover the defect with graft application after receiving a granular bed on the recipient site. Although the patient begins chemotherapy, there were no postoperative complications or delay in maturation of the graft. Evolution of the patient was unfavorable due to the emergence of many skin nodules along the upper limb and lung metastases, the patient passing away in 8 months after surgery.

DISCUSSION

Large excision of tumoral soft tissues is often complicated by infections, seriously undermined blood supply and venous drainage, tendon exposure, functional impairment. That is why repairing a postoperative skin defect continues to be a challenging problem for plastic surgeons. Direct closure by skin grafting may not be suitable for larger defects due to extensive tension. A variety of techniques are available for achieving tension free closure, including split-thickness skin grafts, skin

flaps, and internal or external tissue expansion (2).

Difficulty of the case is enhanced by diagnostic ambiguity; there are two serious diseases entering into discussion. First, with patient's symptoms and history giving a perfect match is the Stewart Treves syndrome: angiosarcoma, a rare and aggressive tumor with a very poor prognosis associated with lymph edema occurred after ipsilateral mastectomy for breast cancer. Concerning the surgical treatment, there are studies that show that there is no significant difference in survival comparing those initially treated with wide excision and those treated with amputation (3).

Giving the aggressive nature of the tumor, high rate of local recurrence, and tendency for early and multiple metastases, long-term survivorship is rare with a median survival of 2.5 years after diagnosis, most patients dying within 2 years from metastatic disease (4). Although liver and bone metastases may occur, spread of disease to the lung or chest wall is often the cause of death in patients with Stewart-Treves syndrome. We consider that, even if there is no evidence of distant metastases at diagnosis, the neoplasic disease is advanced because of the long time elapsed between the onset of the disease and the time of diagnosis. Surgical treatment can be preceded or followed by radiation therapy. Locally advanced tumors or metastatic forms can be treated with mono or polychemotherapy, on systemic or local administration.

Cases with good response using courses of intra-arterial mitoxantrone (MX) and paclitaxel (PTX) are reported (5, 6). Knowing that long-term survivorship is rare with a median survival of 2.5 years after diagnosis, most patients dying within 2 years from metastatic disease(4), wide oncologic excision with skin graft will give the patient a better quality of life than amputation. Moreover, if the final immunohistochemical test would have shown the tumor is Kaposi sarcoma, knowing that it has a better prognosis than angiosarcoma, the large excision with this type of skin graft would give the patient a satisfactory local healing and comfort.

RETROSPECTIVE STUDY ON THE ETIOLOGICAL SPECTRUM AND ANTIBIOTIC RESISTANCE IN INFECTIONS ASSOCIATED WITH OSTEOSYNTHESIS MATERIALS (Abstract): **Aim**: To determine the prevalence of infections according to their etiologic spectrum and antibiotic sensitivity in patients with or without implants and endoprostheses. **Material and methods**: This retrospective study was conducted based on a customized study protocol on 773 cases admitted to the Clinic of Orthopedics – Traumatology of the Iași "Sf. Spiridon" Emergency Hospital in the interval January 1, 2003 - December 31, 2011 for postoperative infectious complication. **Results**: *S. aureus* was more frequently found in the patients without implant (58.2%) and in those with subcutaneous implant (45.5%); the lowest frequency was noticed in the patients with endoprosthesis (27.1%), the frequency distributions showing marked statistically significant differences (p=0,001). *P. aeruginosa* was more frequently detected in the patient group with endoprosthesis (30.2%), while in the other groups it was found in approximately 7% (p=0.001). The presence of *Acinetobacter* spp. was significantly higher in patients with deep implant (12.9%), with the lowest frequency noticed in the patients without implant (4.5%) (p=0.029). Of the total isolated and identified types, 59.6% were non-multidrug-resistant (non-MDR), the remaining 40.4% being MDR types. **Conclusions**: *S. aureus* was the most frequent etiological agent in patients with or without cutaneous implant (45.5 and 58.2%, respectively), and *P. aeruginosa* (30.2%) in the endoprosthesized patients. Implementation of a preoperative screening protocol for the identification of healthy *S. aureus* carriers (Methicillin-sensitive *S. aureus* - MSSA / Methicillin-resistant *S. aureus* - MRSA) and subsequent decolonization would be an efficient way of reducing the incidence of infections caused by this bacterium. **Keywords**: PERIPROTETIC INFECTIONS, BIOFILM, IMPLANT, MRSA.

Postoperative infections still represent a major issue, both for clinicians and general population. In particular, traumatology is a branch of surgery that uses a large variety of implants to treat various fractures (1). Recent data suggest that the proportion of infection is most of the times underestimated. This is accounted for by the fact that

the causative agents may escape detection, either because they are not found in a sufficiently large number to be identified or are strongly adherent to the implant and thus difficult to diagnose using phenotypic microbiological methods (2).

The fact that antibiotic prophylaxis improves the results of endoprosthetic replacement and lowers the complication rate, aseptic loosening and osteolysis included, supports the current hypotheses which state that microorganisms might play a larger part than initially thought (3). Certain comorbidities, such as rheumatoid arthritis, hyperglycemia, obesity, deep vein insufficiency, defective diet, immunosuppression, and prior surgical interventions on the affected limb further increase the risk of infection (4).

MATERIAL AND METHODS

A retrospective analysis of the 773 cases with postoperative infections complications admitted the interval January 1, 2003 - December 31, 2011 to the Clinic of Orthopedics – Traumatology of the Iasi "Sf. Spiridon" Emergency Hospital. A customized study protocol was used to reviewed data regarding: sex, rural/urban residence, type of surgical intervention, causative agent, spectrum of antibiotics resistance, and associated risk factors.

The study patients were divided into two groups according to the absence or presence of an implant. Depending on the fracture site and type o surgical intervention, the patients in the first group (with implant) were divided into three study subgroups: subgroup 1 – 257 patients who had superficially located osteosynthesis materials (clavicle, elbow, tibial plateau, ankle, foot); subgroup 2 – 286 patients who had deeply situated osteosynthesis materials (humeral, femoral, tibial); subgroup 3 – 96 patients with knee and hip arthroplasty. The patients in the second group (without implant, 134 patients) formed subgroup 4.

The samples for bacteriological testing were processed in the Bacteriology Laboratory of the Iaşi "Sf. Spiridon" Emergency Hospital following the standard protocol. At a later stage, depending on the result of antibiogram carried out using the Kirby-Bauer method, the identified bacterial types were classifies as non-MDR and MDR (multidrug resistant) using the CLSI (*Clinical and Laboratory Standard Institute*) criteria. The basic criteria used for this classification came from an international group of experts who, at the initiative of the European Center for Disease Prevention and Control (ECDC) and of the Center for Disease Control and Prevention from USA (CDC) created a standardized international terminology in which the resistance profile for *S. aureus*, *Enterococcus* spp., *Enterobacteriaceae*, *P. aerugonosa* and *Acinetobacter* spp are described (5).

SPSS 17 was used for the statistical data analysis. The data were analyzed and expressed in terms of average values, percentages, and standard deviation.

RESULTS

In the study group 479 patients (62%) were males. Gender distribution showed a statistically significant difference (χ^2 = 44,276; GL = 1, $p < 0.01$).

Of all strains isolated from patients, depending on the microscopic classification, 61.84% were Gram positive cocci, 35.19% Gram negative bacilli, and 2.98% Gram positive bacilli. According to tinctorial affinity, a statistically significant difference was recorded (χ^2 = 402,926; GL = 2, $p < 0.001$).

In the study cases there was an increased rate of *S. aureus* infection (43.5%), a rate of approximately 10% being recorded for *P. aeruginosa* (9.7%) and *Acinetobacter* spp. (9.6%), and below 10% for the other causative agents (between 0.1% for *Morganella* and 7.8%, for *Enterococcus*) (fig. 1).

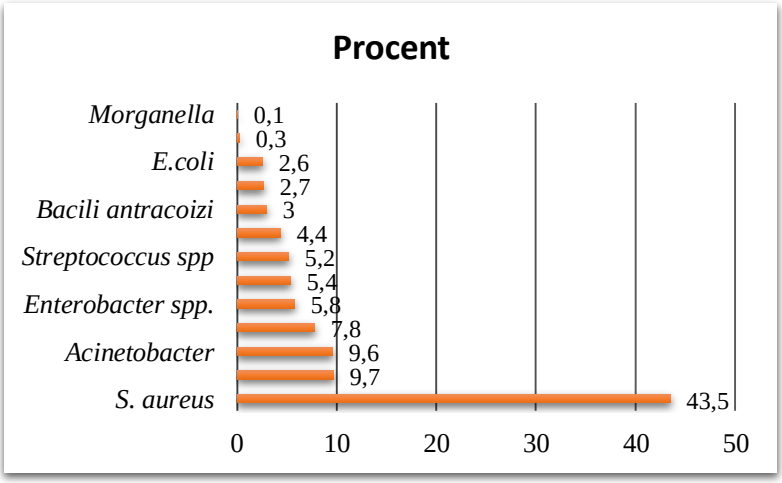

Fig. 1. Distribution of cases according to the causative agent

The proportion of cases with closed fractures infected with *S. aureus* was significantly higher compared to open fractures (44.7% *vs.* 31.4%; p=0.045). The majority of patients infected with *Enterococcus* spp. (7.1% *vs.* 14.3%; p=0.033) and anthracoid bacilli (2.6% *vs.* 7.1%; p=0.049) had open fractures.

With regard to antibiotic resistance, only 59.6% of all isolated and identified strains were non-MDR, the remaining 40.4% being multidrug resistant types (fig. 2).

Of the total number of patients who underwent implant surgery, 29% required the ablation of osteosynthesis material due to the impossibility to eradicate infection by irrigation, debridement and intravenous antibiotic therapy which had good results in most cases (71%). The distribution of patients according the ablation of osteosynthesis material showed a statistically significant difference (χ^2 = 111,56; GL = 1, p < 0.01). Of the total number of implanted patients, the highest rate of ablation was recorded in subgroup 2 (17.20%), followed by subgroup 1 and 3 (8.3% and 3.6%, respectively).

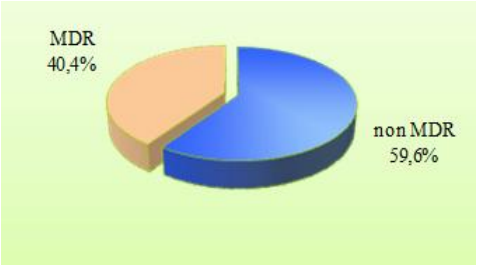

Fig. 2. Distribution of cases depending on the antibiotic resistance

One of the reasons was the involvement in infection etiology of a MDR strain. In all the three implant subgroups, the frequency of MDR strains was higher than that of non-MDR strains: 5.01% as compared to

3.29% in subgroup 1, 9.37% as compared to 7.82% in subgroup 2, and 2.5% as compared to 1.1% in subgroup 3.

As to the presence of the causative agent, assessed depending on the study subgroup, the following differences stand out:

- *S. aureus* was more frequently identified in the subgroup without implant (58.2%) and in the subgroup with subcutaneous implant (45.5%); the lowest frequency of *S. aureus* was noticed in the subgroup with endoprosthesis (27.1%), the frequency distributions showing statistically significant differences (p=0.001);
- the presence of *S. epidermidis* was reduced in all subgroups (p=0.566), the lowest frequency being recorded in the subgroup without implant (3%), and the highest in the subgroup with subcutaneous implant (6.2%);
- *P. aeruginosa* was more frequent in the subgroup with endoprosthesis (30.2%), while in the other subgroups the rate was of approximately 7% (p=0.001);
- the presence of *Acinetobacter* spp. was significantly higher in the subgroup with deep implant (12.9%), while the lowest frequency was noticed in the patients without implant (4.5%) (p=0.029);
- *Enterococcus* spp. was identified with frequencies ranging between 6.7 – 8.4% in all study groups (p=0.942);
- *Enterobacter* spp. was found in 10.4% of the patients with endoprosthesis and in 6.3% at those with deep implant, but the percentage differences were not statistically significant (p=0.138);
- the frequency of *Klebsiella* spp. presence was of 5.1% in the subgroup with subcutaneous implant and below this value in the other study subgroups (p=0.390);
- anthracoid bacilli were more frequently found in the subgroup with subcutaneous implant (4.7%) while in the subgroup without implant it was of 1.5%, with no statistically significant differences (p=0,249);
- in the study cases, *Streptococcus* spp. was found with a frequency ranging between 4 and 7%, without significant differences between the study groups (p=0.696);
- *Proteus* spp. was found most frequently in patients with deep implant (3.5% of the cases) (p=0.703);
- the frequency of *E. coli* was reduced in all subgroups (0.7%, in the subgroup without implant and 3.8% in patients with deep implant) (p=0.210);
- the highest antibiotic resistance (47.2%) was demonstrated by the study in the subgroup with deep implant, while the rate of antibiotic resistant cases in the subgroup without implant was of 29.9% (p=0.006) (tab. I).

DISCUSSION

The diagnosis and treatment of infections is complicated on one hand by the bacterial biofilm formation on implant surface and on the other hand because of the increase in the number of multidrug-resistant bacteria as causative agents.

The general incidence of these complications seems to be sex-dependent, with a much higher risk for the male patients.

The frequency of causative agents is variable according to the recently published studies (2012-2013) (tab. II).

The most frequently isolated was *S. aureus,* followed by the gram negative bacilli (*P. aeruginosa* and *A. baumanii*) and *Enterococcus* spp. The bacterial spectrum related to fracture fixation devices seems to differ from that in hip and knee arthoplasty, resembling more to infections occurring in

patients who do not associate fixation devices, and being characterized by a relatively high incidence of *S. aureus* (over 40%) and *P. aeruginosa*.

Species of the *Streptococcus* genus and *Enterobacteriaceae* family are frequently associated with hip endoprosthesis, where surgical incisions in the proximity of the perineum not surprisingly modify the entire etiologic spectrum.

TABLE I

Antibiotic resistance on types of implant

Resistance	Subcutaneous implant (n=257)		Deep implant (n=286)		Endoprosthesis (n=96)		Without implant (n=134)		p
	n	%	n	%	n	%	n	%	
non-MDR	155	60.3%	151	52.8%	61	63.5%	94	70.1%	0.006
MDR	102	39.7%	135	47.2%	35	36.5%	40	29.9%	

TABLE II

Frequency of causative agents compared to data in the literature

Causative agent	Our study	Dresing and col. 2013 (6)	Fernandes and col. 2013 (7)	Mabit and col. 2012 (8)	Peel and col. 2012 (9)
S. aureus	43.5% (18% MRSA)	51.28% (17.61% MRSA)	45% (12% MRSA)	41.7% (7.3% MRSA)	56% (26% MRSA)
S. epidermidis	5.4%	18.72%	5%	15.6%	24%
P. aeruginosa	9.7%	2.12%	8%	6.3%	10%
Acinetobacter spp.	9.6%	-	8%	-	1%
Enterococcus spp.	7.8%	12.35%	9%	4.2%	15%
Enterobacter spp.	5.8%	3.54%	-	6.3%	6%
Klebsiella spp.	4.4%	1.11%	9%	4.2%	3%
Streptococcus spp.	5.2%	1.68%	-	3.1%	4%
Proteus spp.	2.7%	2.12%	5%	2.1%	7%
E.coli	2.6%	4.38%	2%	3.1%	11%

Antibiotic sensitivity testing revealed an increased frequency of MDR strains (40.36%), mainly represented by *S. aureus* (18.11%) and *Acinetobacter* spp. (8.8%). *S. aureus* with a high vancomycin sensitivity, therefore with a low- and high-level of resistance, signaled as early as 1996 and 2001, respectively, was fortunately not identified. Most types of MDR Gram negative bacilli had an increased sensitivity to carbapenem and fluoroquinolones.

The treatment of orthopedic device-related infections most often consists in long term antibiotic therapy and implant ablation. In our study, implant ablation was performed in only 29% of the patients, the remaining patients being treated with intravenous antibiotics and local debridement (71%).

In all patient subgroups, the rate of *S. epidermidis* varied between 2.99 and 6.33%. These microorganisms are part of the commensal skin flora and may be transmitted from the improperly decontaminated surfaces at the level of the soft tissues or bone during intraoperative interventions.

In addition, several intrinsic and extrin-

sic factors could be involved in the pathogenesis of these infections. Intrinsic factors include: age, nutritional status and obesity. In our study, old age was responsible for the infections, although we failed proving it as an independent factor as reported by other studies (10). Old patients frequently associated other risk factors, such as hyperglycemia (6.33%) and other conditions affecting the immune system, such as peripheral venous insufficiency (21.08%), obesity (4.91%) or chronic hepatitis (2.58%).

Obesity is a more common risk factor in knee prosthesis than in hip prosthesis (11). The highest infection rate was noticed in patients with morbid obesity (CMI≥40 kg/m^2)(12). As a rule, some of these patients also have diabetes or peripheral venous insufficiency.

In 2007, Meding et al. identified preoperatively 15% of the patients with diabetes, out of which only 58% were aware of this diagnosis (13).

CONCLUSIONS

Prosthetic infections not only affect patients, but also constitute a complication which increases medical expenses, thus having consequences for the whole medical system through the supplementary expenses they impose.

S. aureus was most frequently found in the subgroup without implant (58.2%) and in the subgroup with subcutaneous implant (45.5%).

P. aeruginosa was more frequently met in the group with endoprosthesis (30.2%), while for the other subgroups the rate was of approximately 7%.

The presence of *Acinetobacter* spp. was significantly higher in the subgroup with deep implant (12.9%), the lowest frequency being recorded in the patients without implant (4.5%).

Antibiotic sensitivity testing showed an increased frequency of MDR strains (40.36%), mainly represented by *S. aureus* (18.11%) and *Acinetobacter* spp. (8.8%).

The management of orthopedic device-related infections requires further studies in order to identify as quickly as possible the microorganisms responsible and their antibiotic sensitivity, as well as the associated risk factors in view of implementing effective prevention measures and a proper treatment and thus reducing the hospitalization costs and, last but not least, improving patient quality of life.

Future multicentre studies might identify all relevant risk factors for such infections, and thus a proper diagnosis and treatment algorithm. We believe that the implementation of a preoperative screening protocol for the identification of healthy *S. aureus* carriers (MSSA/MRSA) and subsequent decolonization would be an efficient way for reducing the incidence of infections caused by this bacterium.

ANGIOTENSIN-CONVERTING ENZYME AND ALZHEIMER'S DISEASE PREVENTION

Alzheimer's disease (AD) is characterized by neuronal loss and cognitive decline caused by cerebral accumulation and aggregation of amyloid β protein (Aβ) associated with an inflammatory reaction determined by the reactive astrocytes and activated microglia. The most commonly form of Aβ in AD is a neurotoxic peptide with 42 amino acids (Aβ1-42). Accumulation of Aβ1-42 is caused by overproduction or by insufficient clearance. The immune system cells and the peptidases are implicated in Aβ1-42 clearance. Angiotensin-converting enzyme (ACE) is a peptidase with multiples functions. ACE is responsible by vasoconstrictor angiotensin II synthesis, but also by Aβ1-42 degradation in the brain. Using a genetically murine model, Bernstein and collaborators, showed that the ACE overexpression in myelomonocytic lineage cells can reduces Aβ1-42, enhances the capacity of immune system to clear Aβ, reduces cerebral inflammation and prevents cognitive decline in mice with AD.These findings prove the role of enhanced immune response in AD prevention (Bernstein KE, Koronyo Y, Salumbides BC et al. Angiotensin-converting enzyme overexpression in myelomonocytes prevents Alzheimer's-like cognitive decline. *J Clin Invest*. 2014. pii: 66541).

QUANTITATIVE AND QUALITATIVE BONE ASSESSMENT OF THE POSTERIOR MANDIBLE IN PATIENTS WITH DIABETES MELLITUS: A CONE BEAM COMPUTED TOMOGRAPHY STUDY (Abstract): Evaluation of mandibular bone features is very important for the diagnosis, treatment planning and management of dental procedures such as osseointegrated implants. **Aim:** To evaluate the bone quantity and quality of the posterior region of the mandible using the CBCT technique for implant planning in patients with diabetes mellitus. **Methods:** Twenty-three patients with diabetes mellitus and 27 control subjects participated in the study. Mandibular bone measurements were performed on the cone beam computed tomography (CBCT) images. One previously calibrated oral radiologist with CBCT experience measured the distance from mandibular canal to alveolar ridge and the distance from bucal to lingual cortical wall. Also, it was assessed the bone quality of each region of interest, by measuring the bone mineral density. The study protocol was approved by the local Ethics Committee. **Results:** The study revealed the presence of significant correlations between bone quality and values of glycosylated hemoglobin and a significant association between patient gender and bone type. There is a significant inverse correlation between the values of cortical and trabecular bone density in the posterior region of the mandible and HbA1c. **Conclusions:** In conclusion the use of CBCT in preoperative bone measurements will help provide valuable information about the quantity and quality of bone before the placement of dental implants. **Keywords:** DIABETES MELLITUS, CONE BEAM COMPUTED TOMOGRAPHY, IMPLANT PLANNING, PREOPERATIVE, QUANTITATIVE ANALYSES, BONE DENSITY, MANDIBLE.

Diabetes mellitus has been associated with the occurrence of a series of complications involving the skeletal system, such as the reduction of bone mineral density, with an increased risk for occurrence of osteopenia and osteoporosis, poor osseous healing characteristics and impaired bone regeneration potential (1).

However, the influence of systemic diseases, such as diabetes mellitus, on the bone quantity and quality of the jaws has been investigated to a minor extent.

Different oral and maxillofacial imaging techniques used for the assessment of bone quantity and quality, as well as localization of the anatomical structures in the

jaws, are indispensable in treatment planning before placement of dental implants.

Cone beam computed tomography (CBCT) become one of the most useful imaging technique for acquiring bone images before performing dental implant surgery and had been increasingly replacing multi slice CT (MSCT), because it provides adequate image quality associated with a lower exposure dose (2 - 4).

Several authors have reported the use of CBCT intensity values as a measurement to assess bone mineral density, which is expressed in Hounsfield units (HU) (5), characteristics that provide important information about the quality of the bone.

The posterior region of mandible may be the implant site requiring the most rigorous assessment of bone quantity and quality because both will directly influence the results of the implant treatment as well as implant stability.

The aim of this study was to evaluate the bone quantity and quality of the posterior region of the mandible using the CBCT tehnique for implant planning in patients with diabetes mellitus.

MATERIAL AND METHODS

The patients were randomly chosen from the Department of Oral Radiology, Faculty of Dental Medicine, "Grigore T. Popa" University of Medicine and Pharmacy, Iasi, Romania who had received a CBCT examination as part of their dental implant planning. The study protocol was approved by the local Ethics Committee.

Quantitative and qualitative assessment was performed on 50 adult patients (28 male, 22 female) with a mean age of 51.3 years (range 41– 67 years). Of those, 23 patients had diabetes mellitus and 27 were non-diabetic, who served as a control group.

During the preliminary screening, patients had to meet the following entry criteria: (a) absence of second premolars and molars in both sides of the mandible; (b) no history of bone grafting at the implant site; (c) no smoking; (d) absence of systemic disease, infections or illness, except diabetes mellitus for diabetic group and (e) no current use of drugs which could influence the bone quality.

All of the study subjects had blood sampling by venipuncture of the antecubital vein, after a minimum 8 hours of fasting, in order to determine glycated haemoglobin (HbA1c) values. In the study it was used a single standardized commercial laboratory to evaluate the HbA1c levels.

The CBCT device used was the PlanmecaPromax 3D Mid (Planmeca OY, Helsinki, Finland). The scans were carried out under the following exposure conditions: 90 kV, 12 mA, and exposure time of 18.3 seconds. Initial and final reconstructions were carried out by Romexis 2.3.1 software (Planmeca, Helsinki, Finland).

One previously calibrated oral radiologist with CBCT experience measured the distance from mandibular canal to alveolar ridge (bone height) and the distance from bucal to lingual cortical wall (bone width). Quantitative evaluations in each case were made using reconstructed sagital sections of CBCTs images for each potential implant site (fig. 1).

Also, it was assessed the bone quality of each region of interest, by measuring the bone mineral density, which was classified in to four groups: D1, D2, D3 and D4. Qualitative evaluations were made using panoramic reconstructions for each region of interest (ROI) (fig. 2, 3). The measurements were performed bilaterally in the

premolar and molar regions of the mandible.

The evaluation was repeated by the same examiner within an interval of 30 days to ascertain the reproducibility of the HU and the area measurements.

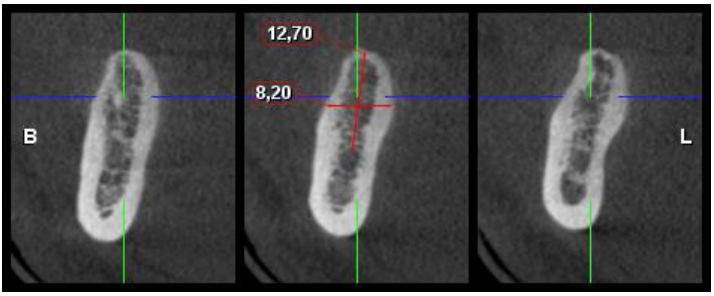

Fig. 1. Measurements of bone quantity (height and width) using sagital images

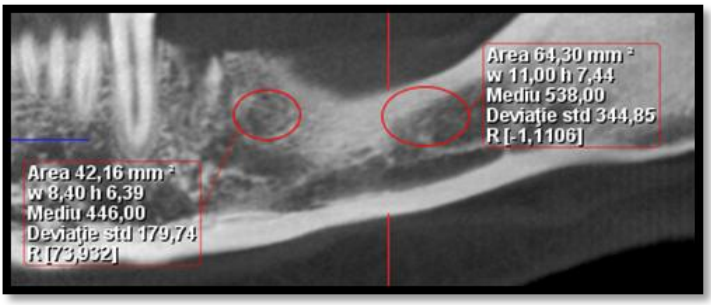

Fig. 2. A reconstructed panoramic CBCT image showing the ROI set in the trabecular bone of the posterior mandible for bone density measurement

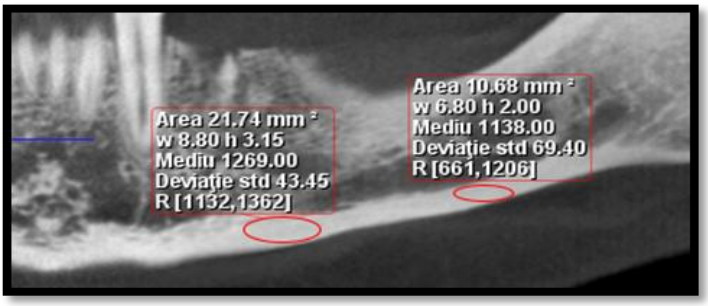

Fig. 3. A reconstructed panoramic CBCT image showing the ROI set in the cortical bone of the posterior mandible for bone density measurement.

The data were analyzed with a statistical software package (*SPSS Version 10.0*; SPSS Inc., Chicago, IL). Mann Whitney U-test was used to measure the differences between bone quantity, quality and those of other parameters (gender, age and HbA1c levels) between diabetes and control groups. The correlation or regression analysis was used

where appropriate. The level of statistical significance was set at P , 0.05.

RESULTS

The patients were stratified on the basis of their HbA1c levels in patients without diabetes (HbA1c level of < 6.0 percent), with well-controlled diabetes mellitus (HbA1c level from 6.0-8.0 percent), with moderately controlled diabetes mellitus (HbA1c level from 8.1-10.0 percent) and with poorly controlled diabetes mellitus (HbA1c level of > 10.0 percent) (tab. I).

The study revealed the presence of significant correlations between bone quality and values of glycosylated hemoglobin (fig. 4).

TABLE I

The distribution of bone quality according to the glycosylated hemoglobin value.

HbA1c (%)	Bone quality				Total
	D1	D2	D3	D4	
≤ 6%	7	20	0	0	**27**
	25.93%	74.07%	0.00%	0.00%	
6.1% - 8%	0	0	8	0	**8**
	0.00%	0.00%	100.00%	0.00%	
8.1% - 10%	0	0	9	0	**9**
	0.00%	0.00%	100.00%	0.00%	
>10.1%	0	0	0	6	**6**
	0.00%	0.00%	0.00%	100.00%	
					50

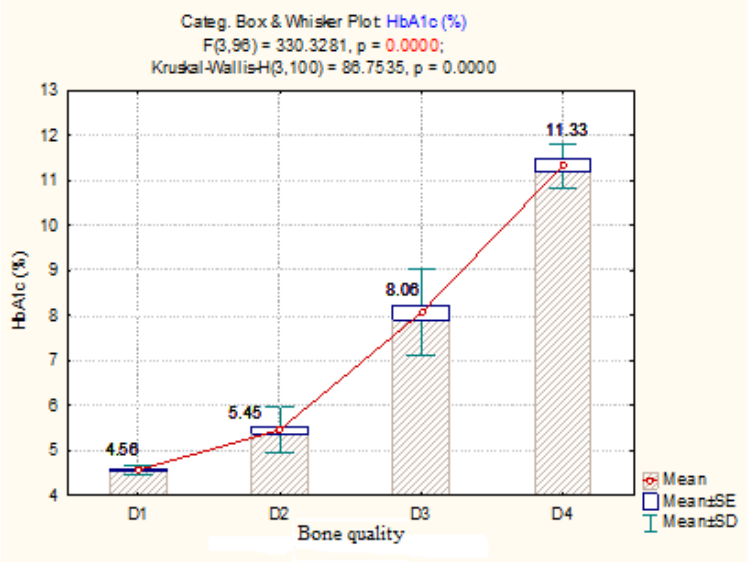

Fig. 4. The mean value for HbA1c (%) levels according to the type of bone

The evaluation of non-parametric correlation showed a significant association between patient gender and bone type. Thus, female patients held a large share of cases from D2 bone type and male patients are found in high numbers in D2 and D3 bone type.

The age showed significantly higher values in patients from D4 bone type compared with the age of patients from D1, D2 or D3 bone type (fig. 5).

There is a significant inverse correlation between the values of cortical and trabecular bone density in the posterior region of the mandible and HbA1c. This result demonstrates that for high levels of HbA1c are found low levels of bone density.

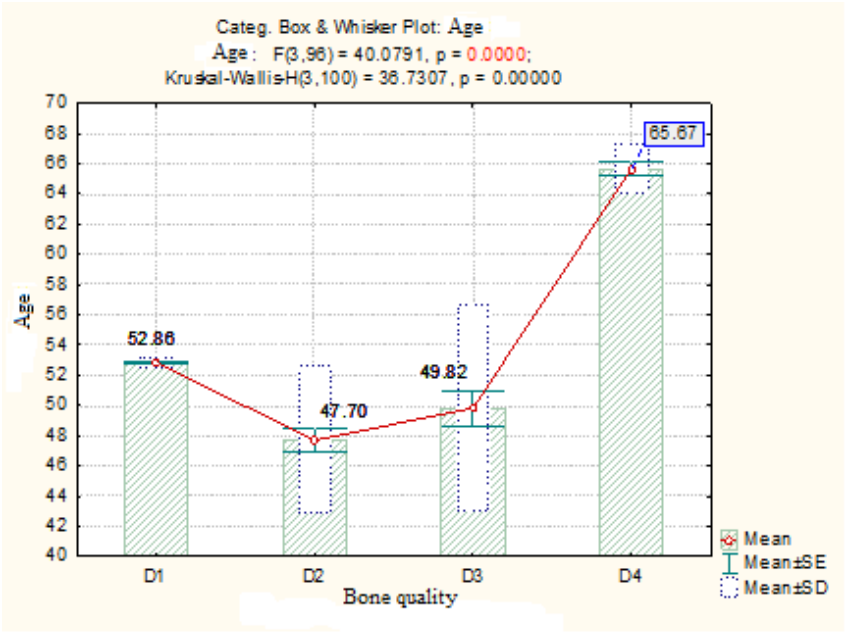

Fig. 5. The mean value of age according to the type of bone.

DISCUSSION

Because of the number of patients with diabetes mellitus, this condition cannot be neglected in the daily routine of dental clinics. The aim of the present study was to assess the mandibular bone quantity and quality in a diabetic patient population, because mandibular bone height, width and density gains special importance in some dental procedures such as osseointegrated implants and grafting.

Well known complications of diabetes mellitus include retinopathy, nephropathy, neuropathy, macrovascular diseases and altered wound healing. Currently it is thought that delayed healing and compromised neutrophil functions are associated with the periodontal diseases, periodontal abscess and implant failures (6, 7).

Mechanisms that might account for an association between diabetes mellitus and bone quantity and quality are not clear. In order to solve the mechanism, several studies have focused on sex hormones, hyperglycaemia, obesity and hyperinsulinaemia, but still the pathogenesis is a subject of

controversy (8). There are few studies evaluating the relationship between diabetes mellitus and mandibular bone quantity and quality. Studies are mostly focused on bone implant problems in diabetic patients. In an experimental study, Nevins et al (9) observed that bone implant contact was significantly reduced for diabetic compared with control animals, but the quantity of bone formation was similar.

Olson et al (10) suggest that the duration of diabetes may be associated with implant failure and their study supports the concept of endosseous dental implant in the mandibular symphysis of type 2 diabetic patients as a predictable procedure.

Recently, the use of CBCT prior to dental implant therapy has contributed to an increasing attention on bone quantity and quality of the jaws.

CBCT has been used in dentistry since 1998 (11). The amount of radiation delivered by this technique is much lower than that used in CT (2 - 4), although the dose of radiation used is at least four times higher than the dose used during panoramic radiography.

Some studies have found that the variable quality of bone is more important to treatment outcome than the quantity of bone in the region of a dental implant. A corrected HU in CBCT data is useful for determining the bone density of ROI prior to implant placement, and this valuable information about bone quality enables better treatment planning by dental practitioners regarding implant positions.

This study clearly demonstrated that patients with diabetes who present poor metabolic control have a low bone density in the posterior region of the mandible.

Bone density of posterior region of the mandible is higher corresponding to premolars are, comparing to molars area. The knowledge of the bone density is very important, the positive outcome for osseointegration depending mainly on it. With this respect, conventional radiographs are not a useful tool.

The mandibular bone quantity and quality clearly reflects the physiological condition of the bone due to systemic diseases of bone degeneration, like diabetes mellitus.

CONCLUSIONS

In conclusion the use of CBCT in preoperative bone measurements will help provide the clinician with a prognostic indicator that not only provides valuable information about the quantity and quality of bone but helps to avoid placement of implants into the very poorest bone, where failure is more likely.

ORAL HEALTH STATUS IN HAEMODIALYSIS PATIENTS

A study realized by a group of indian researchers aimed to assess the oral and dental manifestations in non-diabetic and diabetic uremic patients who were undergoing haemodialysis. The study also aimed to estimate and to compare the salivary pH in the two mentioned groups. Were included ninety seven uremic patients who were undergoing maintenance haemodialysis. Subjective and objective findings were evaluated and recorded. Unstimulated whole salivary pH was recorded by using pH-measuring strips. Dental health assessment consisted of DMFT and CPITN indices. A subjective oral manifestation of dysgeusia was found to be more significant in non-diabetic patients ($p<0.008$). Statistically, a high significance was observed with mucosal petechiae in 31.9% patients of diabetic group .The overall DMFT score was significantly higher in diabetic group. A moderate significance was found with a CPI score of 5 ($p<0.015$). The pH of saliva was significantly higher among diabetic patients. The conclusions of the study showed that the diabetic subjects who were on haemodialysis were at a high risk for developing periodontal disease and they exhibited a potential threat for dental decay and xerostomia. A lower salivary pH and a poor glycaemic control may affect their oral health. (Swapna LA, Reddy RS, Ramesh T, Reddy RL, Vijayalaxmi N, Karmakar P, Pradeep K. Oral health status in haemodialysis patients. *J Clin Diagn Res.* 2013; 7 (9): 2047-2050).

CLINICAL AND EPIDEMIOLOGICAL STUDY ON THE PREVALENCE OF RHEUMATOID ARTHRITIS IN SOME DEMOGRAPHIC STRUCTURES (Abstract): The structure of the epidemiological process of rheumatoid arthritis (RA) is integrated in a broader framework of multiple interactions between intrinsic predisposing factors and the external environmental factors that may have a triggering or stimulating effect. The summative phenomenon is the result of the additive effect of risk factors, the individualized response of body structures and functions, depending on the genetic makeup explain the complexity of the epidemiologic study. **Aim**: To evaluate the epidemiological, clinical and biological features of a series of RA patients. **Material and Methods**: The study included 103 RA patients admitted to the Rheumatology Clinic of the Iasi Rehabilitation Hospital in the interval January, 2010 – December, 2012. **Results**: The analysis of epidemiological data provided information on pre-existing infections caused by the living environment conditions, diet, etc., that may cause damage at cellular and molecular level. **Conclusions**: The present clinical and epidemiological study describes the biological mechanisms and phenomena dependent on physical and social environment. These mechanisms favor and stimulate the occurrence, expansion and development of the disease at population level. **Keywords**: EPIDEMIOLOGY, CHRONIC ARTHROPATHY, INFLAMMATION, PREVALENCE.

Rheumatoid arthritis (RA) is the most common chronic arthropathy in the group of rheumatic diseases. RA has a multifactorial etiology and occurs mostly in women. There is as a pronounced progressive course in RA, which is characterized by exuberant destructive inflammation of the membrane lining the joint cavity, namely, the synovial membrane. The clinical features of RA include pain, joint stiffness, swelling, local heat, and relative functional impairment of the limb whose joints are damaged (3, 4, 5). The group of chronic rheumatic diseases includes RA, ankylosing spondylitis and also degenerative diseases, such as osteoarthritis of the hip, gonarthrosis, arthrosis of the foot, shoulder, elbow and hand; cervical, thoracic and lumbar spondylosis (6, 9, 10). Etiological and predisposing factors of the rheumatic process are found in the physical, biological and social environment, in the ecosys-

tem. The research in the complex field of chronic rheumatic diseases encompasses epidemiological population studies, complemented by immunological, pathophysiological, prevention and therapeutic studies that will provide new information on the risk factors, incidence, prevalence, etiopathogenesis and will facilitate the development of prevention, control and treatment programs with great medical, social and economic benefits (13, 14).

The prognosis depends on the early detection of the disease and on the promptness of therapeutic measures, which take into account the intrinsic factors specific to each patient.

This study aims to evaluate the epidemiological, clinical and biological features of RA in a group of patients receiving care for a chronic rheumatic disease.

MATERIAL AND METHODS

The study included 103 patients (75 females, 28 males) diagnosed with RA, with a mean age of 52.7 ± 12.02 years and average duration of disease of 9.10 ± 7.28 years.

The clinical and epidemiological study aimed to gather, process and analyze data on the prevalence, to evaluate the role of intrinsic and extrinsic factors, to assess the effectiveness of treatment programs, and the economic and social impact of the disease. Study methods included the statistical analysis of clinical and epidemiological data.

RESULTS

It is estimated that RA affects about 1% of the Romanian population and up to 3% of the population aged over 65, which shows that there are approximately 200,000 patients at national level.

Patients included in the study received care in the interval January, 2010 – December, 2012 in the Rheumatology Clinic of the Iasi Rehabilitation Hospital and were monitored and assessed according to a common protocol with multiple parameters.

The study group included 75 female patients (72.8%) and 28 male patients (27.2%). Female / male ratio was 75/28 or 2.67/1. Our findings are in agreement with literature data that show a higher frequency of RA in women, suggesting a possible involvement of endocrine factors in the pathogenesis of this disease (tab I).

TABLE I

Sex distribution in the study group

Sex	Patient no.	%
Male	28	72,8
Female	75	27,2
Total	103	100

Analysis of age distribution shows that RA is most frequent is males aged 50-55 years compared with 60-65 in females.

The mean age of patients included in the study group was 52.7 ± 12.02 years, range 26-77 years. The average duration of RA was 9.14 ± 7.28 years, as patients with recent onset of the disease and patients with a RA history of over 10 years were included in the study (tab II, III, fig 1, 2).

Histogram: AGE

Sex:1 AGE =28*5* normal (x,53.6071,11.5449)

Sex :2 AGE =75*5*normal (x52.3733, 12.2516)

The clinical picture showed the presence of myalgia (32%), muscle weakness (25.2%), muscle fatigue (11.7%), and muscle atrophy (2.9%).

DISCUSSION

The epidemiology of rheumatic conditions is highly diverse as a result of stimulating and varying climatic, social and economic factors. The disabling nature of the disease and the steady development of RA justify the need for a long clinical and epidemiologic follow-up and for comprehensive measures in order to ensure an optimal quality of life.

The area distribution indicates that the highest prevalence is in the urban area. The urbanization phenomenon seems to bring an additional exposure of the body to the action of rheumatogenic factors (6, 9).

The following occupational and workplace factors were evaluated: humidity, temperature fluctuations, physical exercise, sedentary attitudes, noise, etc. The relationship between RA incidence in different parts of Moldova and the geographic and climatic factors shows that although they may be considered non-specific risk factors, they negatively influence the body resistance to disease and promote rheumatogenic mechanisms. For instance, the onset of RA occurred in October and February in 67% of the total number of 103 RA patients. Environmental factors interact with a susceptible genotype and the damaging role of endogenous agents (collagen and IgG molecules) leads to the maintenance of the disease. The medical history taken at the workplace showed a non-uniform distribution of some environmental factors: cold (22.7%), humidity (23.9%), air flow (16.3%), and noise (13.3%) (fig. 3). The housing conditions favored exposure to environmental factors, such as, cold (36.9%), humidity (30.5%) and mold (13.6%) (fig. 4).

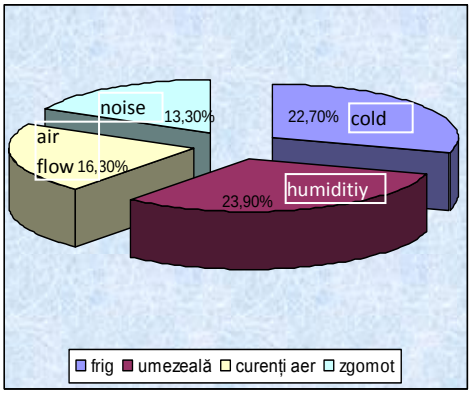

Fig. 3. Medical history showed a non-uniform distribution of some environmental factors

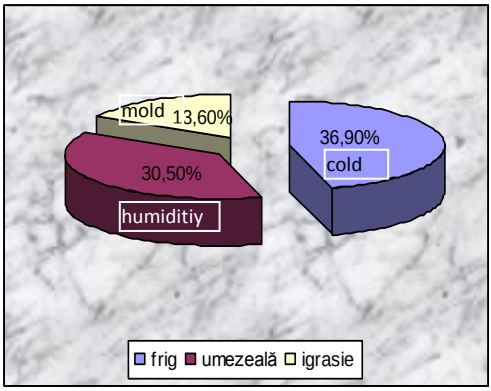

Fig. 4. Housing conditions favored exposure to environmental factors

Chronic joint infections or remote infections have caused RA and no particular infectious agent that could act as a trigger of pathologic processes of the joint was identified. Psychological stress as "a triggering factor" of RA was found in 29.37% of the total number of patients. The psychological stress may be caused by recent stressful events or by a special psychological state. The stress was due to family or employment problems in 23% of the total number of patients. The most common

diseases in the medical history of the patients were viral hepatitis (15.7%), streptococcal angina (24.4%), acute articular rheumatism (3.7%), genitourinary infections (25.2%), and lung disease (7.1%) episodes of acute cholecystitis (10.7%), biliary dyskinesia and gallstone disease (13.2%). Morbidity and mortality rate in RA patients showed a significant decrease following surveillance measures, due to the characteristics of the epidemiological process (9, 10, 15).

Our research has also revealed the insidious onset of RA, with articular manifestations due to the inflammation of the synovial membrane, which is characterized by swelling, pain, local heat, erythema, and limitation of movement.

The distal joints of upper and lower limbs are damaged in RA. Also reported were fatigue, weight loss, myalgia, prolonged morning stiffness, polyarthralgias for weeks or months until the articular manifestations occurred. The articular manifestations are the main feature of RA, namely the symmetry of the damaged joints (13, 14).

The process emerged during a variable period of time and was associated in our study as in the literature with attacks which increase joint pain to the point where disability occurs (3, 9, 11). The mesenchymal structures are painful and many extraarticular manifestations can be seen. The most common RA manifestation was pain of the damaged joints, independent of the intensity of inflammation, and morning stiffness for more than one hour was almost typical.

The damage to the articular structures (bones, ligaments, capsule) and muscle structures induced by the inflammatory immunological process affects to a great extent the functional and professional status of the individual. Complete diagnosis includes the determination of the stage of disease and assessment of deterioration in functional status and ability to work (3,9).

The main complaint of the patients in the study group was pain, which reduces the ability to work due to swelling, deformities and articular ankylosis especially in the upper limb. A proportion of 64.5% of the total number of patients showed symmetrical lesions at onset and they became symmetrical during the first year in 74.5% of RA patients.

Radiological examination findings differed from patient to patient, from osteoporosis to diffuse erosive and destructive phenomena.

Laboratory examinations assessed the inflammatory syndrome, dysimmunitary syndrome, synovial fluid. ESR values were correlated with other tests for inflammation and were a quick evaluation method of patient's state. ESR values ranged between 20 and 50 mm/h, but they have reached 100 mm / h during the inflammatory period or in fast developing forms of RA.

Normochromic or hypochromic anemia was present in most patients and it was characterized by the absence of response to iron therapy, but on the other hand by a favorable response to the use of NSAIDs and blood transfusion. Anemia of chronic inflammatory diseases is part of the syndrome of "hematological stress" induced by activation of macrophages and lymphocytes in response to inflammation. This activation is reflected by excessive iron sequestration in macrophages, increased erythrocyte destruction in the spleen, decreased activity of erythroid stem cells (16). Increased activity of IL-1 stimulates the synthesis of large amounts of apoferritin in the macrophages which sequester the

iron. Lactoferrin in the macrophages, which is synthesized in excess in RA, plays also an important role. Lactoferrin competes with apotransferrin and apoferritin, and it has a high affinity for iron that fixates and blocks iron in macrophages and so the iron becomes virtually unusable during erythropoiesis. Autoantibodies that were investigated are associated with an increased inflammatory process and increased circulating immune complexes (CICs). IgG is significantly increased in all patients and the correlation between the degree of anemia and the increased activity of IgG immune complexes was found in most of the patients (16).

The complex rehabilitation treatment administrated to RA patients was adapted to the clinical and functional stage of RA, psychological characteristics of the patient, social and economic status of the patient, and the results achieved following treatment. The choice of a therapy protocol was made based on tolerance to drugs, co morbid conditions, patient age, which was an important selection criterion because in older people there is a large number of coexisting disorders, acquired at a younger age or later, in old age.

TNF inhibitors (infliximab, etanercept, adalimumab) in monotherapy or in combination with MTX have proved to delay the onset of destruction and deformities in 24.25% of the total number of RA patients.

Patients on long-term glucocorticoid therapy at a dose equivalent to 5 mg prednisone/day or more received calcium and vitamin D. To prevent the decrease in bone mineral density, bisphosphonates (alendronate 70 mg / week), calcitonin (tonocalcin 100 IU / day, 1 vial for 2-3 days), vitamin D analogs (alpha D3 at a dose of 2 tablets / day) were also prescribed (9).

The therapy for degenerative diseases of the locomotor system in the elderly, such as gonarthrosis, cervical spondylosis, coxarthrosis, senile kyphosis, included antiarthritic drugs, namely analgesics and anti-inflammatory drugs. The symptoms were alleviated on a long-term basis by using condroprotective agents.

Kinesiotherapy exercises aimed to preserve or achieve joint suppleness and amplitude, toning of the damaged muscles and to restore the functional synergism, the integration of the joint into the activity of the segment, regional coordination of motility that may lead to social and occupational reintegration (11, 13).

CONCLUSIONS

Our clinical and epidemiological data aimed to identify in a certain demographic sample underlying infectious pathological states typical to RA caused by the living environmental conditions, diet, etc., which may induce disturbances at cellular and molecular level.

RA is a chronic, progressive disease, which in the absence of proper treatment leads to severe joint damage, impaired functional status, physical disabilities and associated visceral lesions that may by life-threatening.

Our study showed the importance of knowing the structural elements of the epidemiological process of RA for the planning of prevention programs to reduce the incidence and prevalence of relapses.

Kinesiotherapy exercises managed to improve physical and mental health of the patients with RA of different stages and severity, achieving a better social and occupational integration or reintegration of these patients by means of a therapeutic educational and rehabilitation process.

NEWS

CYSTATIN C VERSUS CREATININE TO ASSESS THE RISK OF CHRONIC KIDNEY DISEASE

Estimated glomerular filtration rate based on creatinine level was mostly used for staging of chronic kidney disease. Lately, Cystatin C assessment began to be tested as an alternative marker of glomerular filtration function, the advantage being that it not depends on the muscle mass of the patient. We selected a meta-analysis that evaluated 11 studies population (90 750 participants) and 5 cohort studies in patients with chronic kidney disease (2960 participants), all participants benefit from dosing creatinine and cystatin C. Renal function parameters were correlated with the rate deaths (13202 cases in 15 cohorts), cardiovascular deaths (3471 cases in 12 cohorts) and end-stage renal disease (1654 cases in 7 cohorts). The results of the meta-analysis concluded that the introduction of cystatin C values in the formulas for calculating glomerular filtration rate allowed better prediction of risk of death and cardiovascular complications. Thus, the glomerular filtration rate threshold at which the risk of death increases significantly became 85 ml/min/1,73m^2, compared to the known value of 60 ml/min/1,73m^2 body surface area. (Shlipak MG, Matsushita K, Ärnlöv J, et al., Cystatin C versus Creatinine in determining risk based on kidney function, N Engl J Med 2013; 369: 932-943)

Rad52 PROTEIN FUNCTION STUDY BY FLUORESCENCE TAGGING (Abstract): The Rad52 protein plays a significant role in DNA lesions repair by homologous recombination in eukariotic cells. Human Rad52 function somewhat overlaps with BRCA2 and has a role in cell survival in the absence of BRCA1-BRCA2 mediated recombination. Additional Rad52 function analysis and intracellular localization studies are probably necessary. We present a method for Rad22 protein tagging, a *Schizosaccharomycespombe*Rad52 homologue,byCrerecombinase-mediated cassette exchange (RMCE) using the versatile pAW8 plasmid. Rad22 protein was C-termini yEGFP tagged; the resulting strain was analyzed by fluorescence microscopy. The yEGFP signal was observed (Rad22 foci) for 7.5µM camptothecin, 0.005%methyl methanesulfonate, and 4 mMhydroxyurea treated cells. The RMCE method was efficient, and the presence of tagged Rad22 protein was confirmed by Western-Blot and fluorescence microscopy. **Keywords:** RAD52,EGFP,HOMOLOGOUS RECOMBINATION, CASSETTE EXCHANGE.

Rad52 protein plays a central role for DNA lesion repair by homologous recombination (HR) and single strand annealing (SSA). Yeast experiments have proved its role as a recombination mediator and an annealing facilitator (1); however it may be less important for recombination in humans – the breast cancer type 2 susceptibility protein (BRCA2) protein and some RAD51 paralogs may have a similar function (2-3). BRCA2 plays a recombination mediator role by promoting the formation of the RAD51 nucleofilament; it does not retain the single strand annealing function described for Brh2 (*Ustilagomaydis*) and Rad22 (*S. pombe*) in case of replication protein A (RPA) coated DNA strands (4). Therefore RAD52 seems to play an additional role to BRCA2 – double mutants are lethal (5). On the other hand, BRCA2 has been proved to be involved in early lesion repair, while Rad52 seems to have a late intervention involving a blocked or stalled replicating fork. These data suggest human Rad22 involvement in single strand annealing repair (6).

Recent studies showed Rad52 to play a role in cell survival in the absence of BRCA1-BRCA2-mediated homologous recombination, thus Rad22 may be a thera-

peutic target for BRCA deficient cancers (7). Rad52 function studies required fluorescent tagging - a technique enabling microscopical visualization - and mutant's development for the protein domains study.

This paper presents the method for Schizosaccharomycespombe Rad22 (human Rad52 ortolog) carboxi-terminal tagging with enhanced green fluorescent protein (yEGFP) usingCre-mediated cassette exchange. The exchange involves a chromosomal cassette containing a selection marker and the *rad22* gene flanked by two sequences loxP/loxM3 and a cassette (*rad22*-yEGFP) between lox sites from a Cre expressing pAW8 plasmid (8).

MATERIAL AND METHODS

For Rad22 C-terminal tagging we cloned the *rad22* gene without STOP codon from a wild type *S. pombe* as a SphI/SpeI fragment. The fragment obtained was introduced in pAW8_rad22 plasmid by digestion and ligation. A linker-yEGFP-loxM3 was subcloned as a SpeI/BamHI fragment from pAW8E*Nde*I-cyEGFP plasmid (GenBank: JF340116.1) in the new plasmid. Finally, we obtained pAW8_CyEGFP_ rad22 and CyEGFP-rad22 strain as well.

The cloning of rad22 gene without STOP codon as a SphI/SpeI fragment. We cloned rad22 as a SphI/SpeI; we amplified rad22 from a wild type strain with primers rad22_F aaaa*gcatgc*TAATTACGAAAATCCTTTAATTCAAATAAAATTTTGTTTT and rad22_NOSTOP_R aaaa*actagt*TCCTTTTTTGGCTTTCTTATCCA. The PCR reaction contained 10 ng DNA template, 1 µM primers, 0.2 mMdNTPs, 10x KOD Polymerase buffer, 3 µl MgSO4, and 1 µl KOD HotStart DNA (Novagen). The total volume was 50 µl. The PCR program: 94°C for 3 minutes followed by 30 cycles of 94°C 30 seconds, 55°C 20 seconds, 72°C 60 seconds. The PCR product was run in an agarose gel 1% and the gel purified (Machary Nagel kit). The digested fragment was purified and cloned inpAW8_rad22 plasmid. The new pAW8_rad22_NOSTOP plasmid was checked by sequencing.

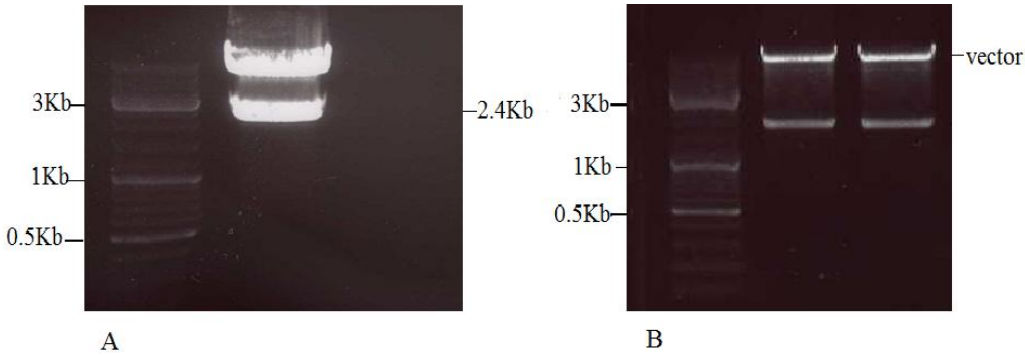

Fig. 1. A. The running of pAW8_NdeI_cyEGFP plamid after digestion with SpeI, BamHI restriction enzymes in order to obtain the insert (linker-yEGFP) for ligation. First line - DNA ladder.Second line - digested DNA.

The construction of pAW8_CyEGFP_ rad22 plasmid. In order to tag *rad22* gene with yEGFP at C-terminus end we have obtained linker-yEGFP-loxM3 as a SpeI/ BamHI fragment from pAW8_NdeI_ cyEGFP (Accession number P30546) (fig. 1A).

A SpeI/BamHI fragment of pAW8_ rad22NOSTOP plasmid (fig. 1B) was changed by the SpeI/BamHI fragment from pAW8_NdeI_cyEGFP. The restriction digestion with SpeI/BamHI enzymes was carried out according to the manufacturer's conditions (New England Biolabs).

B. The running of pAW8_rad22NON-STOP plasmid after digestion with SpeI, BamHI. First line - DNA ladder.Ssecond and third lines - digested DNA.

The vector and linker-yEGFP insert were ligated in a 1:2 ratio using T4 DNA Ligase (New England Biolabs). The resulted plasmid termed pAW8_CyEGFP_ rad22 was transformed into competent *E. coli* DH5alpha cells and the construct confirmed by sequencing (GATC Biotech-Germany).

***S. pombe* transformation and cassette exchange**. The rad22 base strain (loxP-*rad22-ura4*+-loxM3 *ade6-704 leu1-32 ura4-18h*-) was transformed with pAW8_ CyEGFP_rad22 using the lithium acetate procedure as described by Bähler*et al* (1998) (9). The protocol used after transformation was according to Watson (2008) (8).

Western Blot analysis. Protein extraction was performed according to Moreno (1991) (10). After lysis in a Ribolyser (Hybaid), cells were resuspended in sodium dodecyl sulfate (SDS) sample buffer. Proteins were separated in polyacrylamide (10%) by electrophoresis. Western blotting was carried out and the blots were treated with anti-GFP mouse monoclonal antibodies (1/4000) and rabbit anti-mouse IgG-peroxidase antibody (1/5000) (Sigma-Aldrich, USA). The Western-Blot was performed as described by Tanaka (2001) (11).

Visualization of yEGFP signal in Cy-EGFP-rad22 strain. We treated CyEGFP-rad22 cells with 7.5 μM camptothecin (CPT), 0.005%methyl methanesulfonate (MMS) and 4 mMhydroxyurea (HU) for 4 hours. Microscopy was performed using the Delta Vision microscope system (Applied Precision, Issaquah, WA). For fixed cells, 10 Z-axis sections at 0.4μm intervals were combined using the softWoRx quick projection program. Cells were collected by centrifugation and suspended in 100 μl of 1 μg/ml Hoechst 33342 and incubated for 5 min at room temperature in the dark. After incubation, 1 ml methanol was added and the tubes incubated on ice for 10 minutes. The cells were pelleted and washed with 1 ml of acetone and pelleted again. 10 μl of the pellet was spotted onto 0.6% low melting agarose. Each set of images for EGFP and Hoechst 33342 signals were obtained at 25–26°C.

RESULTS

In this paper we have tagged Rad22 protein with yEGFP in a *S. pombe* strain using a Cre-mediated cassette exchange protocol for gene replacement. In a "base strain" - Nt-loxP-rad22-ura4-loxM3 -Ct ade6-704 leu1-32 ura4 D-18 a cassette was inserted instead of the *rad22* gene; this cassette consists of *S. pombe*gene sequence and *ura4*$^+$ selectable marker flanked by a loxP site at one end and by a modified heterospecific lox site (loxM3) at the other. Having the cassette at the chromosomal locus in *S. pombe*, the exchange by homologous recombination was achieved by transformation with a plasmid containing the yEGFP tag with *rad22* gene sequence between loxP/loxM3, Crerecombinase gene and a selection marker (*Saccharomyces cerevisiae* LEU1 gene). Recombinants were selected by uracil prototrophy using the reagent 5-fluoroorotic acid (5-FOA) (8).

The new strain was checked using *rad22* gene frame and EGFP downstream primers 5'-3'(rad22_CHK3-AGCTAAACCAGTGCAGAGAAGC, rad22_M_CHKR-GGCGGAAAGAGGATCAAGGT, rad22_-CHK1-GTCTTGGCTTGAGCGTGATTG and rad22_M_CHKR-GGCGGAAAGAGGATCAAGGT). We obtained the right length of PCR fragments (expected length was 1.6 Kb for rad22_CHK3/ rad22_M_CHKR and 2.2 Kb for rad22_CHK1/rad22_M_CHKR primers) from CyEGFP-rad22 strain (fig. 2A).

These fragments cloned from CyEGFP-rad22 strain were sequenced (GATC Biotech-Germany). The results showed the yEGFP sequence in frame with rad22 gene separated by a linker 5'-ACTGGTTCTACAGGATCAACCGGCTCCACGGGGTCG-3' that is translated in a T G S T G S T G S T G S peptide (T - threonine, G - glycine, S - serine) assuring the flexibility of the yEGFP and Rad22 in the new hybrid protein.

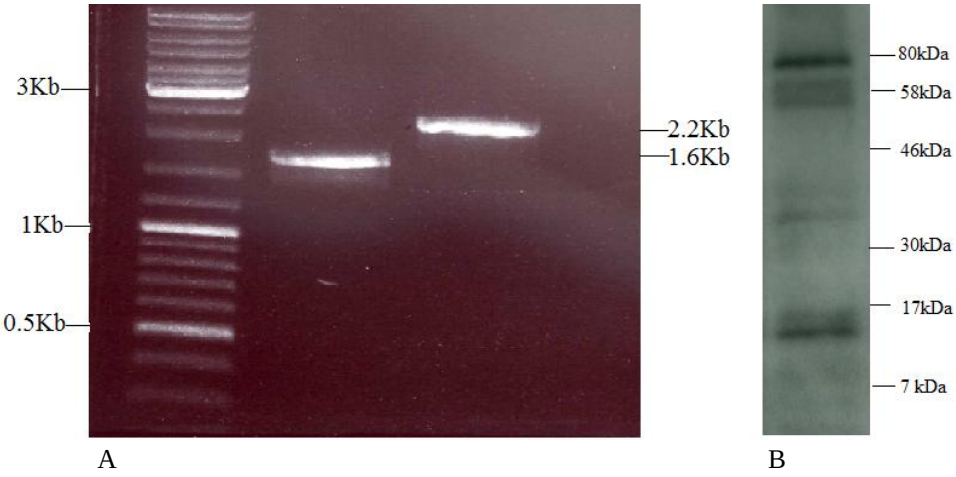

Fig. 2. A. The checking of CyEGFP-rad22 strain by PCR with primers downstream of EGFP sequence and from the gene *rad22*. Line I - DNA ladder, line II - the amplicon obtained with rad22_CHK3 and rad22_M_CHKR primers, line III - the amplicon obtained with rad22_CHK1 and rad22_M_CHKR primers. B. Western Blot of CyEGFP-rad22 *S. pombe* with anti-GFP antibodies.

The Western Blot analysis of CyEGFP-rad22 with primary antibodies (monoclonal anti-GFP from mouse) and secondary antibodies (rabbit IgG anti-mouse – peroxidase**)** revealeda 78.9 kDa protein (the first band) corresponding to the molecular weightof Rad22 and yEGFP (52 kDa + 26.9 kDa) (fig. 2B).

Having the correct sequence of the construct (*rad22-linker-yEGFP*), CyEGFP-rad22 cells were visualized by epifluorescence microscopy. The yEGFP signal was strong allowing us to localize Rad22 protein inside the cell. We could not observe nuclear foci in uninduced cells but distinct yEGFP-Rad22 foci were seen after 4 hours of CPT, MMS and HU exposure (most cells have more than 2 foci) (fig. 3 A,B,C,D).

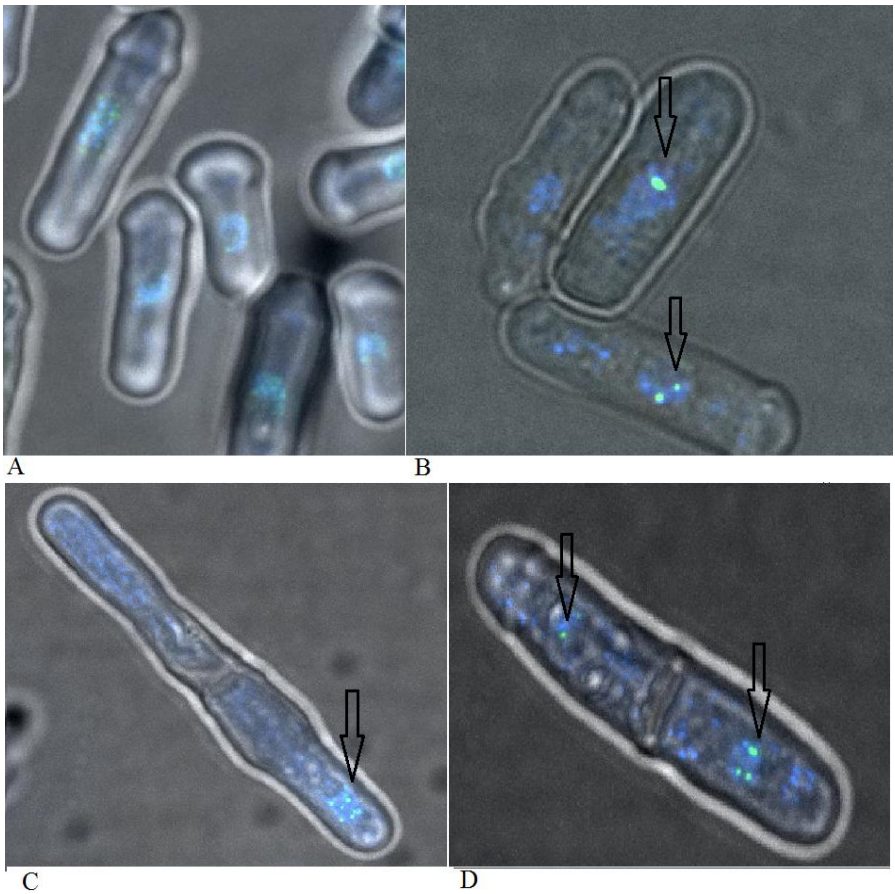

Fig. 3. The yEGFP-rad22 signal of exponentially growing CyEGFP-Rad22 cells observed using a Delta Vision microscope system attached to an inverted Olympus IX70 microscope. Visualization of yEGFP tagged Rad22 in asynchronous, untreated cells (A) and in cells treated 4 hours with 7.5 μM CPT (B), 0.005% MMS (C) and 4 mM HU (D).

DISCUSSION

After obtaining CyEGFP-rad22 strain we treated cells with camptothecin, methyl methanesulphonate and hydroxyurea that affect nucleic acids and alter their function. MMS is an alkylating agent interfering with the DNA replication by modifying the bases of the DNA, HU inhibits the ribonucleotidereductase enzyme reducing the production of deoxyribonucleotides, and comptothecin inhibits the DNA enzyme topoisomerase I. Rad22 protein is involved in DNA repair after genotoxins exposure. We observed CyEGFP-Rad22 nuclear foci after 4 hours of genotoxic (CPT, MMS, HU) exposure reflecting Rad22 centers actively engaged in repair.

CONCLUSIONS

Cre-mediated cassette exchange protocol has proved an efficient and rapid protocol for EGFP Rad22 C-terminal tagging as far as the new hybrid Rad22-EGFP protein retains the repair ability in genotoxins ex-

posed cells. The new strain must be further analyzed comparing it with a wild type strain by other complex methods.

ACKNOWLEDGEMENTS

We would like to thank Prof. A.M. Carr and Dr. A. Watson from Sussex University - Genome Damage and Stability Center for technical support. SURGICAL REVASCULARIZATION IN CHRONIC MESENTERIC ISCHEMIA. CASE REPORTS (Abstract): Chronic mesenteric ischemia (CMI) is a disease causing death either by starvation or enteromesenteric infarction. Diagnosis is often delayed before the patient is referred to a vascular surgery unit. Atherosclerosis is the main cause of CMI. Arteriography is essential in diagnosing CMI and delineating the atherosclerotic lesions. The revascularization procedure consists in an aortomesenteric bypass reconstructing 1-3 visceral arteries. This paper presents two consecutive CMI cases treated at the Vascular Surgery Unit of the Iaşi "Sf. Spiridon" Hospital during 2010. Both patients had symptoms suggestive of mesenteric and aortoiliac diseases. CT angiography revealed specific lesions both for aortoiliac disease and stenotic or occlusive lesions in the celiac trunk and mesenteric arteries. Both cases benefited from aortobifemural bypass surgery using a synthetic graft associated with aortic-superior mesenteric artery bypass with reversed vein graft (in the first case both mesenteric arteries were revascularized). Immediate and remote results were favorable, with remission of intestinal symptoms and weight gain. Bypass patency was followed-up by CT angiography and Doppler ultrasound. CMI is a diagnostic and therapeutic challenge. Open surgery provides symptom remission in 90% of cases. Permeability at 5 years is 80-90% for open surgery, higher than by endovascular therapy. Average permeability of the two types of intervention is 70% at 5 years, similar to the infraaortic bypasses. **Keywords:** MESENTERIC BYPASS, CHRONIC MESENTERIC ISCHEMIA, AORTOBIFEMORAL BY PASS

Chronic mesenteric ischemia (CMI) is a disease causing death either by starvation or entero-mesenteric infarction. The diagnosis is often delayed prior to patient referral to a vascular surgeon.

The pathophysiological mechanism underlying CMI is the failure to achieve normal postprandial mesenteric hyperemia.

Hemodynamicaly, significant arterial stenosis causes attenuated postprandial response leading to imbalance between required and available O_2 and metabolites causing postprandial pain (mesenteric angina).

Atherosclerosis is the main cause of visceral artery occlusive disease and consequently the cause of CMI. Other occasional causes are: fibromuscular disease, aortic dissection, neurofibromatosis, rheumatoid arthritis, Takayasu disease, postradiotherapy lesions, Burgers Disease, systemic lupus erythematosus and drug use (cocaine, ergot) (1).

The abdominal digestive tract is supplied by three major arterial axes (celiac trunk, superior and inferior mesenteric arteries) interconnected by an extensive collateral network. Usually, a significant occlusion of 2 or 3 visceral vessel is required for the patient to become symptomatic. But isolated occlusion of the celiac trunk or superior mesenteric artery (SMA) alone can give rise to symptoms when the collateral network is inefficient (1).

There are 3 stages of CMI: chronic intermittent ischemia, permanent ischemia and enteromesenteric infarction (2).

The patient complaints are: intestinal angina (30-60 min postprandial), weight loss caused by food phobia (fear of eating), altered bowel function, bloating, or vague abdominal discomfort, diarrhea or constipation (2).

Patients with CMI frequently have concomitant renal or aortic artery occlusive disease.

Arteriography is essential for confirming the diagnosis and delineating the lesions topography (3).

Late studies are controversial with respect to: the type of surgery (open surgery *vs.* endovascular surgery), endarterectomy *vs.* antegrade/retrograde bypass, number of bypassed vessels (1-2-3), the best type of graft (synthetic *vs.* venous - internal saphenous vein / superficial femoral vein) (1).

Studies in the United States revealed that mesenteric bypass represents less than 0.5% of all peripheral vascular bypasses (1).

CASE REPORTS

This paper presents two consecutive cases of CMI treated at the Iaşi, Vascular Surgery Unit, during 2010.

CASE 1

G.A., 51-year-old male presented with the following complaints: postprandial abdominal pain, significant weight loss, frequent loose stools, loss of appetite, significant fatigue, intermittent claudication and decreased walking perimeter (< 50m).

Laboratory tests revealed hypoproteinemia (total proteins = 56 g/dl) and hypoalbuminemia (albumin = 2.53 g/dl).

Preoperatively CT angiography confirmed the suspicion of CMI revealing severe celiac trunk stenosis of about 12 mm from the origin and atherothrombotic occlusion in the initial segment of SMA of about 20mm, occlusion of the left internal iliac artery and its branches, and also the atheromatosis of the abdominal aorta, iliac arteries and abdominal aorta branches (fig. 1).

Fig. 1. Preoperative CT angiography - Patient G.A

Pre-surgical screening was performed and anticoagulant, vasodilator and hypolipemiant treatment was administered.

The surgical intervention consisted in a deep aortic bifemoral bypass with Dacron graft associated with an aortic–inferior mesenteric artery (IMA) and aortic- superior mesenteric artery (SMA) bypass with

autologous venous graft.

Through median laparatomy we entered the left mesenteric–colic space. The abdominal aorta was exposed by dissecting the peritoneum from the ligament of Treitz to the IMA. The left renal vein was identified as a landmark for locating the renal artery and SMA (fig. 2).

The next step was the i.v. administration of 5000 U Heparin. After 5 minutes the infrarenal aorta was clamped proximally and distally. An aorto-bifemoral bypass was performed using a Dacron graft. All anastomoses (syntetic graft to aorta and synthetic graft branches to femoral arteries) were termino-lateral (fig. 3).

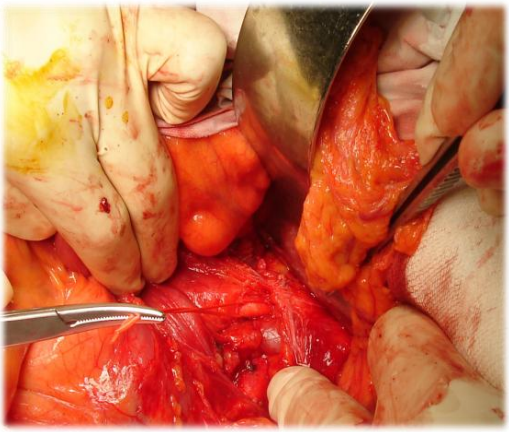

Fig. 2. SMA with vessel loop

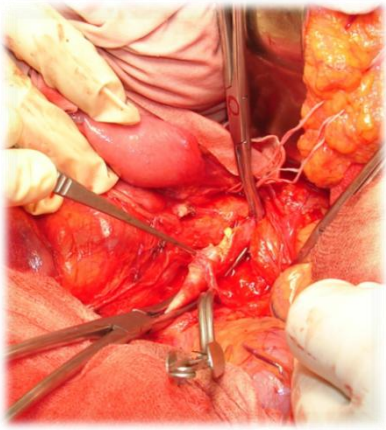

Fig. 3. Clamped aorta. Longitudinal Aortotomy. Significant Atherosclerosis

The next step was to perform the aortic – IMA and SMA bypass with reversed autologous vein graft previously harvested (fig. 4, 5).

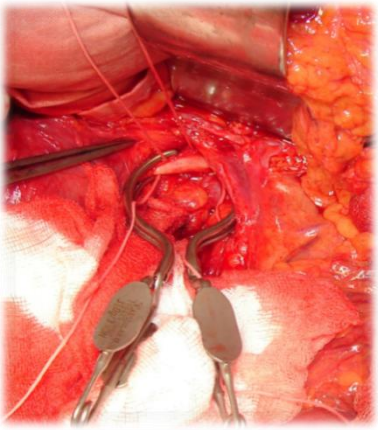

Fig. 4. Clamped AMS

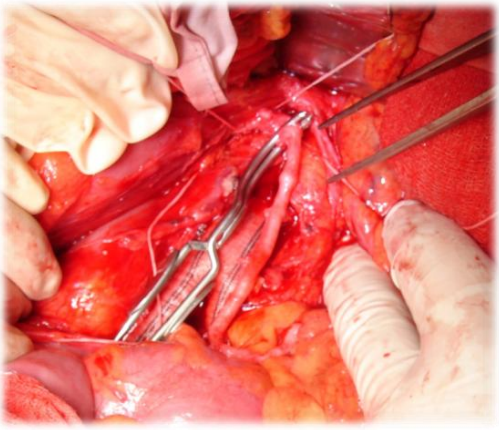

Fig. 5. Proximal T-L aortic-AMS anastomosis

We aimed to adjust the length of the graft to allow its positioning in relaxed “C" position (fig. 6, 7).

The omentum was brought in the aortomesenteric space by coloepiploic detachment. This way the omentum was used as an anchor fringe (fig. 8).

After surgery the patient received the three "A" therapy (antibiotic, anticoagulant, analgesic) associated with vasodilators and hypolipemiant agents.

Immediate and remote results were favorable: warm skin, bilateral popliteal pulse, bilateral Doppler signal along the anterior tibial artery, remission of the abdominal pain, oral feeding after gas transit was resumed, and bowel transit.

A control CT angiography was performed 2 weeks after surgery (fig. 9). It showed that the aortobifemoral and aortomesenteric bypasses were patent. The echo-Doppler follow-up at 1, 2, 3, 6 and 12 months revealed persistent graft patency (fig. 10, 11).

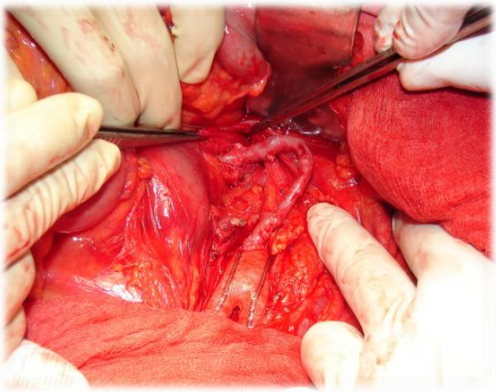

Fig. 6. Aortic-SMA bypass (“relaxed C”)

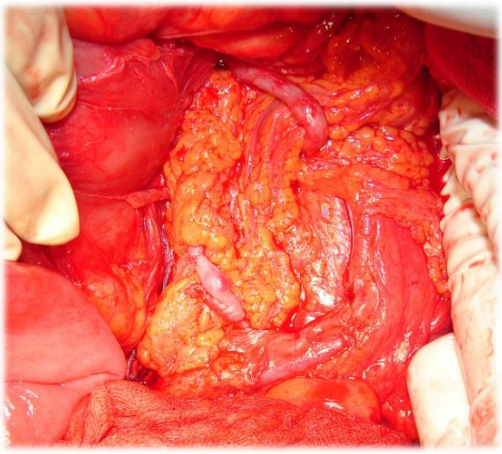

Fig. 8. Epiploic anchor fringe

Fig. 9. Postoperative CT angiography

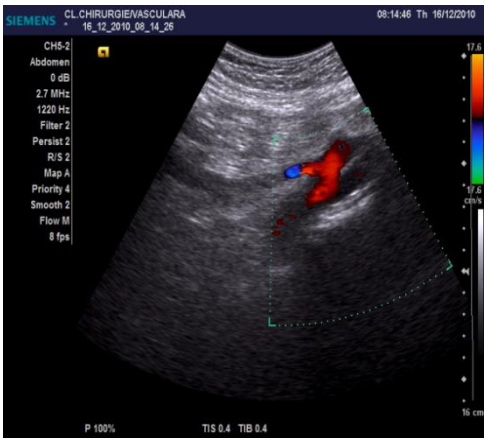

Fig. 10. Color echo-Doppler graft patency

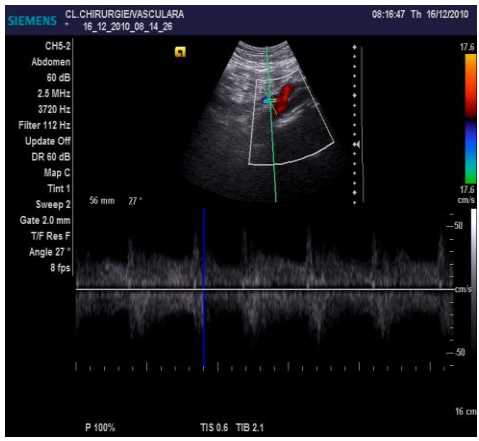

Fig. 11. Superior mesenteric graft blood flow signal

CASE 2

C.G., 60-year-old, male was admitted to the Vascular Surgery Unit complaining of intermittent claudication of both lower limbs (more intense in the left limb), decreased walking perimeter (<50 m) and significant weight loss.

Laboratory findings revealed the absence of the inflammatory syndrome and presence of hypoproteinemia. Doppler signal was detected from the peripheral arteries of the lower limbs.

Preoperative CT angiography revealed abdominal aorta with multiple calcified atherosclerosis plaques and parietal thrombosis, iliac artery with multiple stenosis, thrombosis of the origin of celiac trunk bifurcation (the remaining vessels being patent) and significant SMA stenosis from the origin (fig. 12).

Fig. 12. Preoperative CT angiography. Patient C.G

Fig. 13. Postoperative CT angiography Patient C.G

The surgical intervention consisted in an aortobifemoral bypass with Dacron graft associated with an aortic – SMA bypass with reversed vein graft (right internal saphenous vein) (fig. 13, 14).

The surgical technique was similar to that used in the first case except that only one mesenteric artery was revascularized (fig. 15).

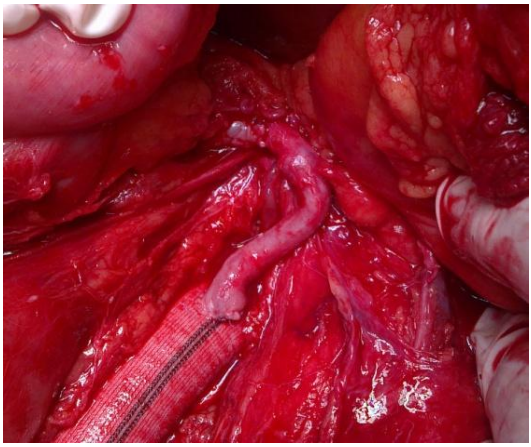

Fig. 14. Aortic-SMA by pass ("relaxed C").

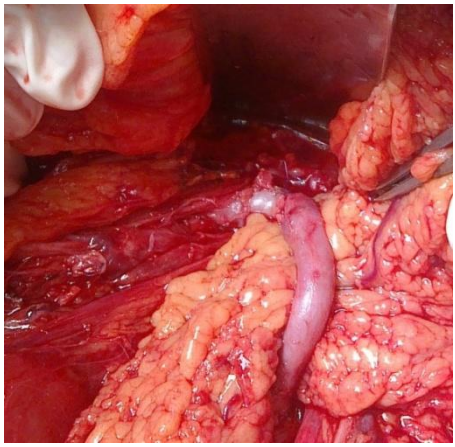

Fig. 15. Epiploic anchor fringe

Immediate and remote results were favorable: presence of pulse in the lower limb peripheral arteries and resumption of physiologic bowel transit.

This case also benefited from CT angiographic control along with Doppler ultrasound follow-up at 1, 2, 3, 6 and 12 months that revealed the patency of the bypass.

DISCUSSION

The diagnosis and treatment of CMI is challenging. Revascularization of the mesenteric artery alone is difficult without replacing the aorta with a synthetic graft and proximal anastomosis rather impossible. Longitudinal aortotomy reveals atherosclerotic material with high probability of embolism.

Present standards are based on the study by Kruger et al. (4) - 12% perioperative morbidity and 2.5% perioperative mortality. Higher values were observed for the simultaneous reconstruction of the aorta, complete revascularization (three branches) and preoperative renal failure.

The remission of symptoms along with weight gain is achieved in 90%-100% of cases (5). The 5-year patency is 80-90% for open surgery (1, 4, 6). Permeability is higher with open surgery than endovascular therapy, with an average for both of 70%, similar to that of bypasses for peripheral revascularization (1, 6).

CONCLUSIONS

Both our cases were successfully treated, no complications being recorded in the immediate postsurgical period and after a 2-year follow-up. The two patients presented for symptoms of aortoiliac disease and CMI, respectively. With appropriate surgery both problems were solved and the patients were reinserted into their families and society.

TREATMENT OF PERI-IMPLANTITIS USING MULTIPLE APPLICATIONS OF CHLORHEXIDINE CHIPS: A DOUBLE-BLIND, RANDOMIZED MULTI-CENTRE CLINICAL TRIAL

Universal strategies for managing peri-implantitis are yet to be adopted. The aim of this study is to examine a protocol of intensive application of chlorhexidine containing chips in sites with peri-implantitis. This multi-centre, randomized, double-blind, parallel, two-arm clinical trial included 60 patients (77 implants) with probing depth (PD) 6-10 mm and bone loss ≥2 mm around 1-2 implants. One to two weeks following scaling and root planing, baseline measurements were made followed by implants' debridement. Patients were randomized to receive matrix chips (MatrixC) or chlorhexidine Chips (PerioC). Measurements and chips placement were repeated at weeks 2, 4, 6, 8, 12 and 18. At 6 months, patients returned for final examination. Probing depth reduction was greater in the PerioC (2.19 ± 0.24 mm) compared with MatrixC (1.59 ± 0.23 mm), p = 0.07. Seventy percentage of the implants in the PerioC and 54% in the MatrixC had PD reduction ≥ 2 mm. Likewise, 40% of the sites (PerioC) and 24% (MatrixC) had PD reduction ≥ 3 mm. Clinical attachment level gains for both groups were significant; however, the changes in the PerioC group were significantly greater than in MatrixC [2.21 ± 0.23 mm. and 1.56 ± 0.25 mm respectively, p = 0.05]. Bleeding on probing was reduced by half in both groups. These results suggest that frequent placement of PerioC and MatrixC together with implants debridement resulted in a substantial improvement in sites with peri-implantitis. Further studies will be required to fully appreciate the mechanism of this treatment (Machtei EE, Frankenthal S, Levi G, Elimelech R, Shoshani E, Rosenfeld O, Tagger-Green N, Shlomi B. Treatment of peri-implantitis using multiple applications of chlorhexidine chips: a double-blind, randomized multi-centre clinical trial. J Clin Periodontol 2012; 39(12): 1198-205).

2. IIIrd Surgical Clinic

THE RISK OF LYMPHEDEMA AFTER BREAST CANCER SURGICAL TREATMENT (Abstract): The **aim** of this study is to emphasize the importance of knowing the predisposing factors of the occurrence of homolateral upper limb lymphedema after breast cancer surgery. **Material and methods:** The study included 1104 patients with breast cancer, who were hospitalized in the IIIrd Surgical Clinic, Iasi, between 2000 and 2010, for surgical treatment followed by oncological adjuvant therapy. The surgical intervention was conservative in 228 cases and modified radical mastectomy – Madden type - in 876 patients. Periodic clinical follow-ups were done every 3 months during the first postoperative year, every 6 months during the second year and annually thereafter. **Results:** Early lymphedema occurring in the first 14 postoperative days or between day 14 and day 21 was found in 8 patients. Late lymphedema, occurring up to 12 months or more after surgery, was diagnosed in 41 patients. Medium and severe lymphedema occurred at 42 patients. We evaluated the preexisting risk factors, the risk factors related to the type of surgery and those related to the cancer staging. **Conclusions:** It's ideal to identify predisposing factors of developing lymphedema related to breast cancer surgery before applying any type of treatment. There are therapeutic methods (general, drug therapy, physiotherapy) and methods related to the surgical act that influences the prophylaxis of lymphedema or have an amazing effect on already occurred lymphedema. **Keywords:** UPPER LIMB LYMPHEDEMA, BREAST CANCER, AXILLAR ADENOPATHY

Multiple statistics consider that lymphedema secondary to surgical treatment of breast cancer has an incidence ranging from 3 to 87% (1). This difference between statistics can be explained by different criteria, the presence of some difficulties in the measurement methodology, the duration of the follow-up of the patients and, not least, through a series of individual particularities of the patients. The risk of developing lymphedema in women treated for breast cancer in The United States of America is expected in more than 2.5 million patients (2). Lymphedema may also occur after conservative surgery of the breast cancer associated with the biopsy of the sentinel lymph node, the percentage reaching up to 23% (3), but with an average of 6%, as 15 studies on 4241 patients show (4,5). The occurrence of lymphedema has multiple consequences: on the upper limb functional status and breast status (for

lymphedema occurring after conservative surgery), the quality of life, the work integration, the relationship with family members (related to lifestyle changes, the self perception in terms of personal independence, the patient considering that she has an invalidity in what her aesthetic appearance is concerned) the risk of erysipelas , sometimes with a relapsing character and not least with important financial consequences (long term medication and therapeutic methods, often expensive). Of course, the studies have a follow-up period ranging from 3 months to 20 years, without a basic value (9). The aim of this study is to find, at a lot of patients treated for breast cancer, the risk factors of the occurrence and progression of lymphedema. Another objective is to analyze the value of preventive methods for upper limb lymphedema in relation to the surgical treatment sequence for breast cancer.

MATERIAL AND METHODS

The study included 1104 patients with breast cancer aged between 26 and 93 years who were hospitalized and operated by the same surgical team between 2000 and 2010. 178 patients were in stage I and II and 926 patients in stage III and IV. The surgical treatment was conservative - quadranectomy with axillar lymphadenectomy in 228 patients and modified radical mastectomy (Madden operation) was performed on 876 patients. All the patients were treated with fractionated heparin and micronized flavonoids (Detralex) or procianidolic oligomers, flavan derivatives (Endotelon), starting with the first day after the surgery for a period of 7 to 21 days. All patients had elastic compression of the chest and arm for 14 postoperative days. The patients began the adjuvant chemotherapy between for 21-30 days after surgery and the radiotherapy –when indicated - up to thirty days after the last infusion of chemotherapy. Our study only took into consideration the lymphedemas from the IInd and IIIrd degree (42 patients) according to the International Society of Lymphology (9).

All the patients were supervised by the same surgical team; the clinical periodic evaluations were performed every 3 months during the first year after surgery, every 6 months during the second year and annually thereafter. Every 6 months we performed an ultrasound examination (bilateral axillary region, bilateral supraclavicular region, bilateral breast region in case of conservative surgery and breast and pectoral region in case of Madden operation). The clinical evaluation also focused on the measurement of the forearm and of the arm circumferences.

RESULTS

From 42 cases of severe and medium lymphedema, in 8 cases (19.04%), we found that an early lymphedema appeared in day 14 after the surgery and between 14 and 21 postoperative days. The late lymphedema that appeared after day 21 after surgery can be divided into 2 categories: lymphedema occurring during the first postoperative 12 months (9 cases) and lymphedema occurring later than 12 postoperative months (25 cases) (tab. I, fig. 1).

Regarding the impact on the patient's clinical condition, we found pain, a feeling of weight in the upper limb and decreased motility of the upper limb (48% of cases). 3 patients with important and persistent lymphedema presented almost a total motor deficit of the affected upper limb. We also evaluated the impact of that lymphedema

of the upper limb had on the state of mind of these patients. Therefore 21 patients had obsessive-phobic concerns related to the absence of the breast, the already installed lymphedema and concerns regarding the fear of recurrence of the disease. 4 of these 21 patients developed depression and were guided to see a psychiatrist.

TABLE I

Risk factors for medium and severe lymphedema after breast surgery related to patient's status

Severe/ medium lymphedema (42 cases)	Age ≤ 45 years	Age > 45 years	BMI- normo-ponderal	BMI I-II obesity	BMI morbid obesity	Same dominant arm	Trauma/burns on same arm	Smoking
No. of cases	8	36	2	38	2	41	6	13

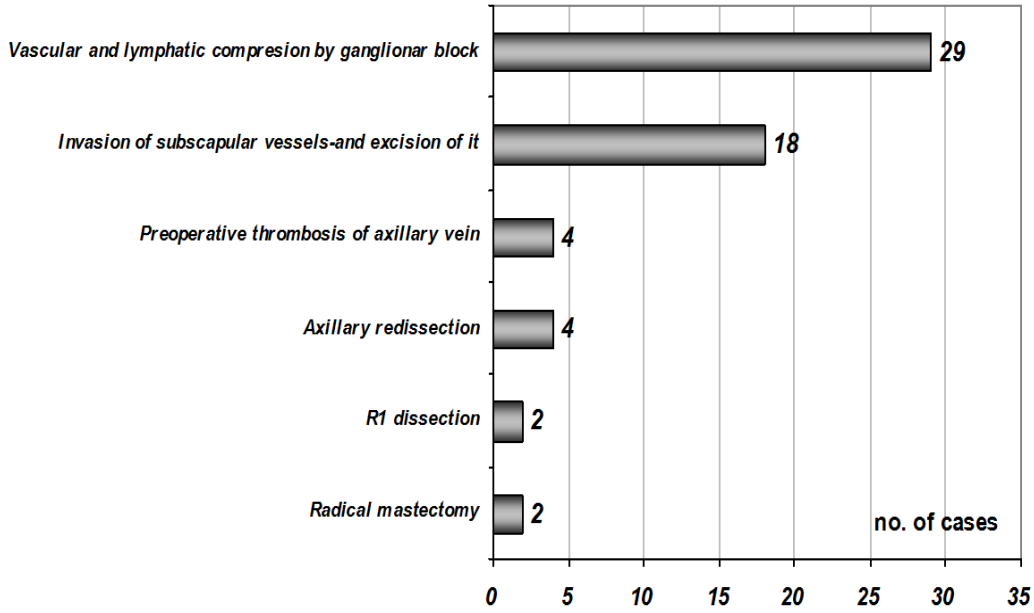

Fig. 1. Risk factors for medium and severe lymphedema after breast surgery related to the extension of the cancer and surgical treatment

DISCUSSION

The current study refers to 42 cases of medium and severe lymphedema, with the following objectives: the assessment of the incidence of postoperative lymphedema in the studied group, the assessment of the risk factors for lymphedema, determining the occurrence interval of postoperative lymphedema, monitoring the degree and the evolution of the lymphedema under different therapeutic methods and estimation of the duration of patient surveillance.

It would be ideal to identify predisposing factors of developing lymphedema before applying any therapeutic methods in order to inform the patient on this possible complication and to apply more precise prevention methods before surgery.

Elder women seem to be more prone to lymphedema – as the majority of the studies show (6, 7, 8) as we also found in our research. We concluded that the extent of mastectomy has no great influence on the occurrence of the lymphedema as other studies also observed (10). Moreover, the results of some studies highlighted that the lymphedema was present in 37% of the cases when axillary lymphadenectomy was performed, 8% of the cases with dissection of the lower third of the axillary lymph nodes and 5% related to the biopsy of an axillary lymph node (10). Other studies observed that women who underwent sentinel lymph node biopsy followed by radiotherapy, had an increased risk of developing lymphedema when chemotherapy regimens were based on anthracyclines (11).

Higher body weight with a BMI over 25kg/m^2 and thorough lymph node dissection were associated with a higher incidence of lymphedema, a fact that is also found in literature.

In the studied group we found that the excision of the axillary lymph node relapse or the redissection of the lymph nodes (in cases of incomplete axillary dissection on a previous surgical intervention) and the dissection of an encapsulated lymphatic collection adjacent to the axillary vein were associated with a medium lymphedema. We also found that the dissection of the fatty tissue around the axillary vein was associated with a higher risk of lymphedema of the homolateral upper limb. This may be due to the removal of some derivative lymphatic pathways traveling close to the vein; there is also, in these cases, a venous stasis and a fibrous tissue organized around the axillary vein, causing its strangulation. Postoperative axillary vein thrombosis that occurred especially after the dissection of the lymph nodes adherent to the vein and preoperative vein thrombosis due to the presence of tumor thrombus are other factors responsible for stasis and edema; in these cases, lymphedema is associated to venous edema. As an argument, we noticed that in those cases when the axillary vein was occluded (by the tumor thrombus or by the lymph nodes), when we managed to spare the subscapular venous package as a derivative pathway, through the intercostals veins, we had no lymphedema, in comparison with those situations in which the subscapular veins were resected together with the axillary ganglionar block.

There are studies showing that postoperative lymphedema is related to the lymph node tumor invasion. On our patients we found that when the lymph node dissection was complete, without residual tumor and with the spearing of the fatty tissue around the axillary vein, the incidence of postoperative lymphedema was 0 and that's because the tumoral invaded lymph nodes did not serve for lymph drainage anymore and there already were derivative pathways. In those cases when we had residual tumor, we usually had postoperative lymphedema.

There is still a controversy regarding the prevalence of lymphedema in the dominant upper limb (13, 14). For our study this element is only relevant in the case of patients declaring the occurrence of lymphedema after physical effort. The occurrence

of lymphedema is related to lymph nodes invasion (12). On the analyzed casuistry we noticed that when in cases when the ganglionar tumor invasion was important, when the limphadenectomy was Ro and when a ganglionar fatty tissue around the axillary vein could be kept, then there was no lymphedema. In the cases where there has remained a ganglionar tumor tissue around the axillary vein as well as at those with detailed dissection around the axillary vein, the lymphedema appeared. The explanation is: in the first case the tumor invaded nodules were not useful at the drainage of the lymph, which found other derivative paths; in the second case the edema that appeared had an important venous component by wrapping the axillary vein with the tumor remains that continued growing. The prophylactic administration of micronized flavonoids and derivatives of flavani for a period of 14 to 21 days starting with the first day after surgery together with the administration of fractionated heparins decreased the incidence of lymphedema. Meanwhile, in patients who developed postoperative lymphedema, we prolonged the administration of this medication associated with elastic compression of the upper limb, gymnastics and maintaining of the upper limb in an elevated position turned severe edema into mild edema. Another factor that led to severe lymphedema remission was the decreasing of the body mass. We also paid attention to the nutrition of the patients by recommending a diet that does not significantly increase the lymphatic flow; the patients are advised to consume foods containing medium chain triglycerides. Another prophylactic method related to the surgical act is to identify the main lymphatic pathways from the upper limb by preoperative infiltration of methylene blue in the forearm, this being able to protect the main lymphatic collectors that transport the lymph from the upper limb to the thoracic duct.

Surgery for lymphedema had no significant long time results. Excisions of subcutaneous fat had been practiced, but postoperative infections and poor cosmetic results were discouraging. Partial excision of subcutaneous fat and ”burying” a skin flap – without epidermis – under the arm muscle aponeurosis was tried by some of us, but without favorable results. More recently, liposuction has been practiced through several small incisions, with relative good results in 12 months of patient surveillance (15). Lympho-venous anastomoses showed good results in 50-77% of patients (16). The results seem to improve when lymph-venous anastomosis was associated with excision of subcutaneous tissue.

CONCLUSIONS

Our study shows that preoperative detection of risk factors for upper limb lymphedema in breast cancer would allow the early and intensive application of targeted therapeutic methods. On the other hand, avoiding aggressive and excessive dissection around axillary vein and maintaining the body fat surrounding axillary vein would limit collateral damage to the lymphatic system and diminish the risk of lymphedema.

Our paper show a relevant factor: micronized flavonoids associated with methods of physical therapy from an early stage provide a good prophylaxis for lymphedema occurring after breast cancer surgery. Patients should avoid extensive physical effort of homolateral upper limb and should

be thought the methods that can sometimes prevent recurrent erysipelas in the upper limb, thus avoiding severe lymphedema installation.

ANTHROPOMETRIC PARAMETERS - PREDICTIVE FACTORS FOR CARDIO-METABOLIC DISEASES (Abstract): The **aim** of this study was to evaluate comparatively the predictive power of body mass index (BMI) and waist circumference (WC), two anthropometric parameters used in daily practice, for detecting cardio-metabolic diseases, in a rural community in north-east Romania. **Material and methods:** We evaluated 3248 persons, aged 19 or over, for whom we collected the following data: medical history, anthropometric parameters, blood pressure value and biochemical parameters. **Results and conclusions:** Both WC and BMI help correctly determine the presence of arterial hypertension, diabetes and dislipidemia. However, the cut-off value of each of these parameters differs for each pathology. The predictive value of WC for different cardio-metabolic diseases is maintained even at normal or borderline overweight values of BMI. **Key words:** WAIST CIRCUMFERENCE, BODY MASS INDEX, PREDICTIVE POWER, CARDIO-METABOLIC DISEASES.

The medical community admits as certain the epidemic progression of obesity and acknowledges the risks for morbidity, disability and mortality associated with excess weight (1). Energy imbalance causes various diseases, but those with cardio-metabolic echo warned international fora, causing mobilization of scientists to establish effective programs for prevention and treatment of these people. Data published in the literature have demonstrated the importance of location of excess fat at abdomen level (2), assessed by WC, even for people with BMI within normal limits (parameter recognized by the World Health Organization for diagnosis of obesity) (3). The purpose of this study was to assess comparatively the predictive power for cardio-metabolic diseases of the two anthropometric parameters used in daily practice, BMI and WC.

MATERIAL AND METHODS

We included 3248 persons in our study aged 19 or over, who lived in Deleni, Iaşi County, enrolled in the interval July 2007 – July 2008. We collected the following data for each subject: medical history, anthropometric parameters, blood pressure values and biochemical parameters – fasting glycaemia, total cholesterol, HDL cholesterol, triglycerides. Measuring weight and height

were performed under light clothing and fasting, using calibrated instruments, standardized and calibrated according to international standards. Determination of weight status was based on BMI (BMI = weight/height^2, kg/m^2) and WC was measured midway, between the lower rib margin and the anterior superior iliac spine. Diagnosis of hypertension was set at values >140 mmHg systolic and/or >90 mmHg diastolic and / or antihypertensive treatment. Diabetes was present when fasting blood glucose ≥126 mg/dl and in those with known diagnosis. Diagnosis of dyslipidemia was based on the values of fasting lipid fractions: total cholesterol, HDL cholesterol and triglycerides, and/or specific previous treatment. Diagnostic limits for each were: total cholesterol >200 mg/dl, HDL cholesterol <50 mg/dl in women or <40 mg/dl in men, triglycerides >150mg/dl. Statistical analysis of data was performed using *Statistical Package for Social Sciences program* (*SPSS*) version 16.0.

RESULTS

The study included 3248 people, of which 1341 men (41.28%) and 1907 women (58.71%), aged between 19 and 91 years, mean age 50.58 ± 18.26. We have conducted previous epidemiological studies in this population and the findings were published in literature: the prevalence of obesity (BMI ≥ 30 kg/m^2) 17.5% (n=570) (4), hypertension 31.1% (n=1010) (5), diabetes 5.2% (n=169) (5), hypercholesterolemia 42% (n=1364) (5), decreased HDL cholesterol 13.6% (n=442) (0.3% in men, 13.3% in women) (5), hypertriglyceridaemia 19.6% (n=637) (5).

Based on these data, we compared the predictive power of the two anthropometric parameters (BMI and WC) for the development of one of the co morbidities listed. We used as statistical method the Receiver Operating Characteristic curve (ROC curve), which is formed by representing sensibility (Se - maximum value 1) and specificity (Sp - maximum value 1) for the entire range of variation in the predictor (WC or BMI in our case). We then analyzed, comparatively, the predictive power of WC and BMI for the development of hypertension, diabetes mellitus, hypercholesterolemia, low HDL cholesterol and hypertriglyceridaemia.

The data obtained have statistical significance; hence both WC and BMI help determine the correct presence of hypertension, diabetes and dyslipidemia. There were differences however in the limit value of each of the anthropometric parameters as predictors for each co morbidity. Thus, analyzing the ROC curves we saw the following optimal predictive values: for hypertension, cut-off values were: 25.5 kg/m^2 for BMI, 98 cm for WC (fig. 1); for diabetes, BMI = 27 kg/m^2, WC = 100 cm were cut-off values (fig. 2); for hypercholesterolemia, BMI = 25 kg/m^2, WC = 96 cm were cut-off values (fig. 3); for low HDL cholesterol, BMI = 26.9 kg/m^2, WC = 99 cm were cut-off values (fig. 4); for hypertriglyceridaemia, BMI = 26.2 kg/m^2, WC = 99 cm were cut-off values (fig. 5).

DISCUSSION

In modern societies, energy imbalance manifests in various ways in every individual, causing frequent and important co morbidities, among which some life threatening diseases such as coronary or cerebrovascular disease, sleep apnea syndrome. The most evident rapidly modifiable parameter is weight status, often meaning the accumulation of excess fat which is dysfunctional. This leads to excess secretion of proinflammatory adipocitokines which are responsible for the increased cardiometabolic risk of these people. In this context and in the light of the obesity epidemic, global interest in the medical world has turned to finding quick and cheap ways of early identification and assessment of individuals with cardio-metabolic risk. Our previous studies have shown not only a

high prevalence of overweight in this community in northeastern Romania (4), but also of comorbidities with cardio-metabolic risk (5, 6).

The current findings indicate that both WC and BMI, two commonly used anthropometric parameters in daily practice, both in primary care and specialty level, help determine the correct presence of hypertension, diabetes and dyslipidemia and, moreover, have the same predictive power for the conditions specified, in the rural population studied. The predictive value of WC for different cardio-metabolic diseases is maintained even at normal BMI, or borderline overweight values of BMI, which emphasizes the importance of location of excess fat.

The results are even more important as the literature increasingly mentions the need to assess both anthropometric parameters to fully characterize people from a cardio-metabolic perspective. Metabolic syndrome, a constellation which implies the presence of several metabolic disorders, has had WC value for a long time as mandatory criterion for diagnosis, reflecting the importance of evaluation of this parameter in practice. In the literature there are numerous published data on the importance of assessing WC. In this respect, a prospective study that analyzed the effects of change in WC on cardio-metabolic risk factors over a period of nine years was DESIR (Data from Epidemiological Study on the Insulin Resistance Syndrome) (7). The study enrolled over 3800 participants aged 30-64 years and showed that after adjustment for BMI, an increase of ≥ 7 cm of WC significantly increased the risk of co morbidities and metabolic syndrome (odds ratio 7.9 (95% CI: 4.4 to 13.9) in men and 4.7 (95% CI: 2.7 to 8) in women), while decreasing at least 3 cm of WC produced significant reduction in triglycerides, insulinemia, the prevalence of metabolic syndrome in both sexes and decreased blood pressure in women.

A recent analysis of the Dallas Heart Study (8) demonstrated that the number of cardio-metabolic risk factors increased with increasing WC, in both women and men, regardless of race. Risk factors quantified in this study were: triglycerides ≥ 150 mg/dl, HDL cholesterol < 40 mg/dl in men and < 50 mg/dl in women, insulin resistance defined as HOMA value ≥ 1.63, systolic blood pressure ≥ 130 mmHg, diastolic blood pressure ≥ 85 mmHg or antihypertensive treatment, C-reactive protein ≥ 3 mg/l.

National Health and Nutrition Examination Survey (NHANES III study), reference study regarding the health of the population, showed that the value of WC correlates better than BMI with four of the five examined risk factors: LDL cholesterol, HDL cholesterol, hypertension and hyperglycemia (9). Moreover, evidence from this study showed that WC is an independent risk factor for developing type 2 diabetes, being a stronger predictor than other cardio-metabolic risk factors (LDL cholesterol, HDL cholesterol or triglycerides) or than BMI, for the condition (10). Also, several recent studies have shown that visceral obesity and its metabolic complications are not only found in obese individuals, but contribute to increased cardio-vascular risk in normal-weight, apparently healthy people, as well (11, 12). On the other hand, it has been shown that there are obese individuals who are "metabolically healthy", with only a minimal amount of visceral fat (13).

All the evidence suggests that evaluation of visceral fat is a more relevant criterion than the total amount of fat for the assessment of cardio-vascular risk.

A special category is formed by people of normal weight but with phenotypical characteristics of obesity, called "metaboli-

cally obese normal weight". It has been hypothesized that these individuals would be characterized by hyperinsulinemia and / or insulin resistance, hypertriglyceridaemia and hypertension associated with a BMI <25 kg/m^2. Compared with the control group, normal weight metabolically obese subjects have a low insulin sensibility, increased abdominal and visceral adiposity, an atherogenic lipid profile and increased blood pressure (14).

CONCLUSIONS

Our results showed that both WC and BMI had predictive power for the presence of diabetes mellitus, dyslipidemia or hypertension in people from this rural community located in north-eastern Romania. Practically there was no difference between the predictions of WC compared with BMI, both anthropometric indicators being equally valuable in the prediction of cardiometabolic risk factors in the studied population. Therefore, routine measurement of WC, simple and easy to do, can be included in the algorithm for the initial assessment of each individual, in primary care, regardless of BMI.

STUDIU COMPARATIV – INTERVENȚII CLASICE *VERSUS* TEHNICA LICHTENSTEIN ÎN CURA HERNIARĂ

R. Dima
Universitatea din Oradea
Facultatea de Medicină şi Farmacie
Departamentul de Chirurgie
Spitalul Clinic Județean de Urgență, Oradea

COMPARATIVE STUDY BETWEEN CLASSICAL OPERATIONS AND LICHTENSTEIN TECHNIQUE FOR HERNIA REPAIR (Abstract): **The aim** of these study was to compare classical procedures in inguinal hernia repair (Postemski, Kimbarovski, Bassini, McVay) made in the Second Surgery Department of County Clinical Emergency Hospital Oradea with the operations in which was used the Lichtenstein technique in the same department, in a period of two years, with respect to recurrence rate, technical difficulty, convalescence and chronic pain. **Material and methods:** 217 operations were performed in classic way or using the Lichtenstein technique. Follow was performed at 1 month, 3, 6 and 12 months after surgery with a compliance of 80%. **Results:** There was no significant difference in operating time between classic operations and tension free operations. The recurrence rates were significantly lower in the group operated by the Lichtenstein technique. The chronic pain was reported in both groups as mild or moderate. **Conclusions:** Lichtenstein hernia repair was easy to learn took the same time and resulted in fewer recurrences. It is possible to be used successfully in a general surgical unit. **Key words**: INGUINAL HERNIA, LICHTENSTEIN OPERATION, CLASSICAL PROCEDURES

În literatura de specialitate, recurența după chirurgia herniară poate varia între 0,1 şi 20%. Puține alte intervenții chirurgicale prezintă o astfel de variație a rezultatelor (1).

Alterarea metabolismului colagenic are drept urmare slăbirea țesutului fibro-conjunctiv al regiunii inghinale, ducând la apariția herniilor. Utilizarea în intervențiile chirurgicale a acestor țesuturi deficiente, mai ales în condiții de tensiune, va determina o rată crescută a recidivelor. În hernioplastia fără tensiune în locul suturii grosiere a structurilor anatomice, se realizează întărirea peretelui posterior al canalului inghinal prin inserția unei proteze (2, 3, 4, 5, 6).

Scopul acestui studiu este de a compara cunoştințele privind procedurile clasice (Postemski, Kimbarovski, Bassini, McVay) efectuate în Clinica Chirurgie Generală II din Spitalul Clinic Județean de Urgență Oradea, cu operațiile folosind tehnica Lichtenstein efectuate în acelaşi serviciu, pe o durată de doi ani. S-a urmărit evidențierea existenței unor eventuale dificultăți tehnice, rata de recurență, apariția unor particularități ale perioadei de convalescență (prezența şi caracterele durerii cronice postoperatorii) (7, 8).

MATERIAL ŞI METODE

În perioada septembrie 2007 – decembrie 2009, s-au efectuat 217 intervenţii chirurgicale pentru hernie inghinală, dintre care, pentru 73 (33,6%) s-a folosit tehnica Lichtenstein, iar la restul de 144 (66,4%) au fost utilizate procedeele clasice. Vârsta pacienţilor, toţi de sex masculin, a fost cuprinsă între 18 şi 79 de ani (media: 54,5 ± 2 ani). Cazurile studiate au inclus hernii inghinale directe, indirecte, unilaterale şi bilaterale, iar criteriile de excludere au fost reprezentate de herniile femurale, existenţa unor coagulopatii, tratament anticoagulant sau stare biologică improprie. Operaţiile s-au efectuat în anestezie loco-regională sau generală (tab. I, fig. 1, 2).

TABELUL I

Distribuţia cazurilor în relaţie cu vârsta

Vârsta (ani)	Clasic		Lichtenstein	
	Nr.	%	Nr.	%*)
<30	2	1,4	1	1,4
31-40	14	9,7	8	11,0
41-50	33	22,9	19	26,0
51-60	53	36,8	27	37,0
61-70	24	16,7	15	20,5
>70	18	12,5	3	4,1
Total	**144**	**100,0**	**73**	**100,0**
Vârsta medie	**54,5±8,2 ani**		**52,3±7,8 ani**	

*) pentru valorile mai mici de 10, proporţiile sunt orientative

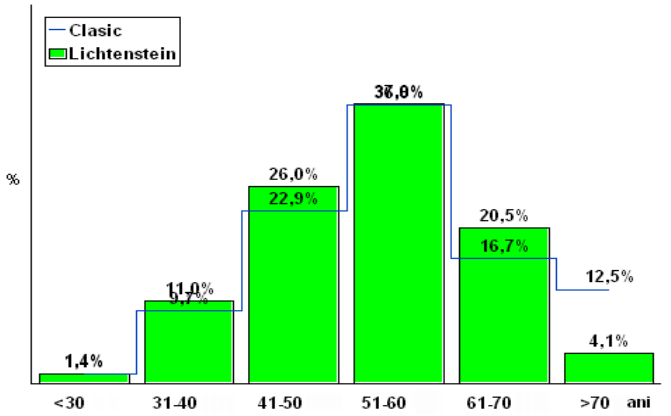

Fig. 1. Distribuţia cazurilor în relaţie cu vârsta

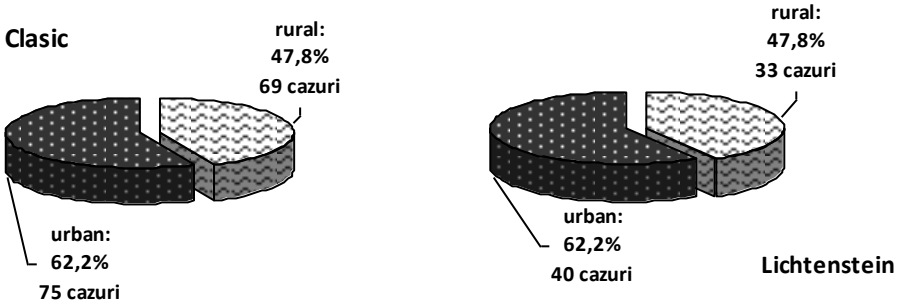

Fig. 2. Distribuţia cazurilor în relaţie cu mediul de proveniență

În herniile indirecte, sacul herniar a fost identificat, disecat de inelul profund şi deschis pentru a permite examinarea conținutului, sacul herniar a fost ligaturat la bază, cu rezecarea porțiunii distale (4).

În cazul aplicării procedurii Lichtenstein, plasa de polipropilenă a fost ajustată pentru a se potrivi dimensiunilor canalului inghinal, fixată la vârf de tuberculul pubic, la ligamentul inghinal şi la tendonul conjunct (5, 6). S-a practicat controlul hemostazei, iar în cazul unor hernii voluminoase, s-a plasat un tub de dren sub aponevroza oblicului extern suturată cu fire separate, urmat de închiderea plăgii.

Îngrijirile postoperatorii au beneficiat de antibioticoprevenție, aproximativ 48-72 de ore, iar la pacienții cu risc crescut s-au administrat heparine cu greutate moleculară mică pentru profilaxia trombozei venoase profunde, cu 12 ore preoperator şi postoperator pe toată durata spitalizării. Analgezia postoperatorie a fost asigurată prin administrarea de antialgice minore. Durata medie de spitalizare a fost de 3 zile.

REZULTATE

Au fost luate în considerație variabilele precum vârsta, tipul de activitate (grea, uşoară sau muncă de birou) şi mărimea testiculului de aceeaşi parte cu hernia. Parametrii preoperatori au fost tipul herniei, anesteziei şi complicațiile postoperatorii. A fost înregistrată durata operațiilor, iar cele de peste 70 minute au fost considerate prelungite (tab. II, fig. 3).

TABELUL II

Distribuția cazurilor în relație cu tipul herniei inghinale

Tipul herniei inghinale	Clasic		Lichtenstein	
	Nr.	%	Nr.	%
indirectă	81	56,3	47	64,4
directă	37	25,7	15	20,5
mixtă	26	18,1	11	15,1

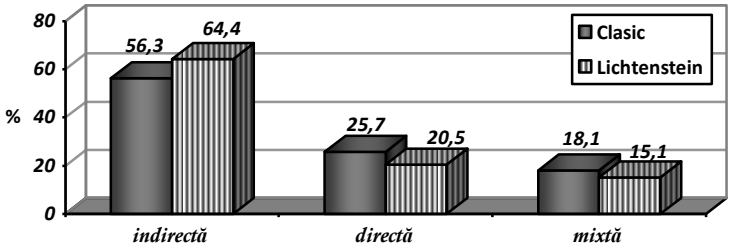

Fig. 3. Distribuția cazurilor în relație cu tipul herniei inghinale

Anestezia regională a fost utilizată în 143 (65,9%) cazuri, cea generală în 61 (28,1%) şi cea regională completată cu generală în 13 cazuri (tab. III, fig. 4).

TABELUL III

Distribuția cazurilor în relație cu tipul anesteziei

Tipul anesteziei	Clasic		Lichtenstein	
	Nr.	%	Nr.	%
Loco-regională	95	66,0	48	65,8
Generală	41	28,5	18	24,7
Loco-regională completată cu generală	8	5,6	2	2,7

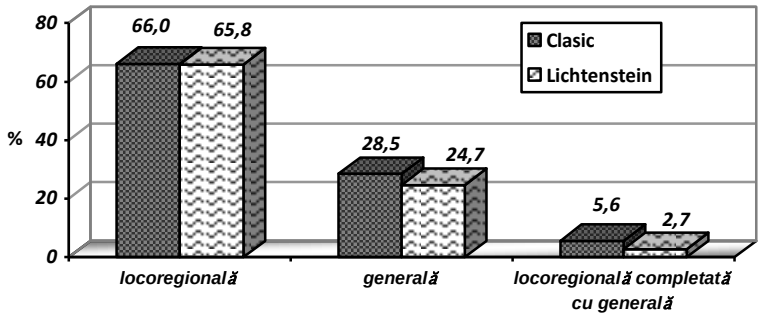

Fig. 4. Distribuția cazurilor în relație cu tipul anesteziei

Durata medie a intervențiilor în care s-a aplicat tehnica Lichtenstein a fost de 55 de minute iar pentru tehnicile clasice a fost de 42 de minute (fig. 5).

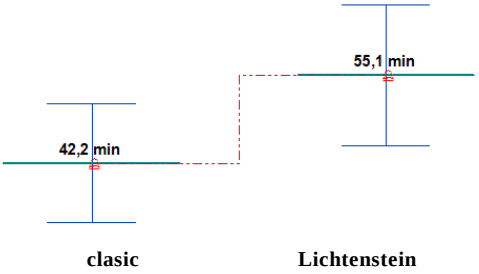

Fig. 5. Durata medie a intervenției chirurgicale

Nu s-au înregistrat complicații majore postoperatorii, dar în perioada imediat postoperatorie, s-au înregistrat 5 cazuri cu complicații la lotul la care s-a practicat operația Lichtenstein (2 hematoame şi 3 seroame); edemul testicular la 3 cazuri cedând ulterior la administrarea de AINS şi drenaj postural. Nu s-au semnalat abcese sau infecții datorate materialului eterogen. Lotul operat prin tehnici clasice a înregistrat 9 hematoame şi 7 seroame. Edemul testicular a apărut la 5 cazuri, atrofia testiculară la 2 pacienți, după 3 şi 6 luni şi 1 caz de orhiepididimită la aproximativ 2 luni postoperator. Dificultăți în urinare care au prelungit perioada de internare s-au înregistrat la 34 de pacienți, dintre care 32 au fost operați sub anestezie regională, iar 17 au necesitat cateterizare uretrală. Durerea postoperatorie a fost măsurată cu o scală vizuală analogă (fig. 6, 7).

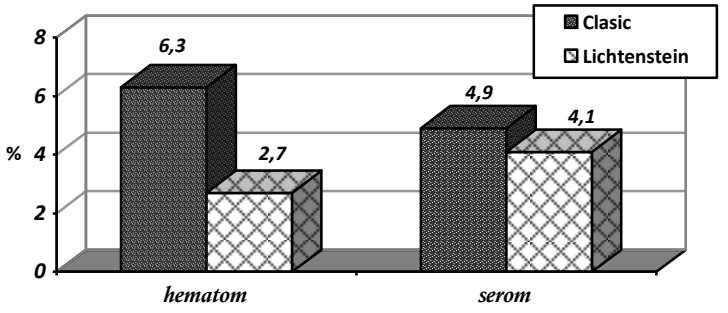

Fig. 6. Distribuția cazurilor în relație cu complicațiile postoperatorii

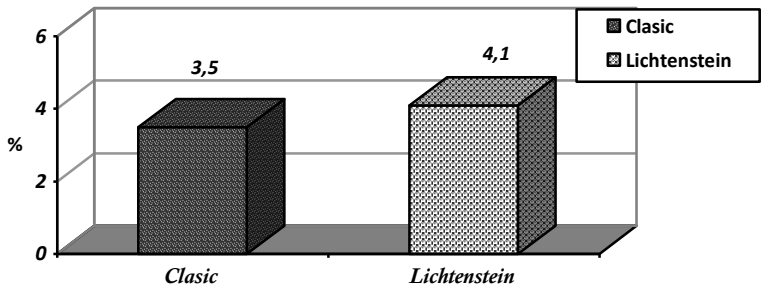

Fig. 7. Prevalența edemului testicular

Urmărirea postoperatorie a fost efectuată la 1 lună, 3, 6 şi 12 luni, cu o complianță de 80%. Pacienții au fost chestionați asupra durerilor persistente, postoperatorii, durata până la recuperarea completă şi numărul de zile de concediu medical. Pacienții care au acuzat dureri persistente de intensitate redusă sau incompletă recuperare au fost reexaminați.

În lotul pacienților operați prin tehnica Lichtenstein s-au înregistrat 5 (6,8%) cazuri cu durere persistentă mai mult de 2 săptămâni, iar în lotul celor operați prin tehnici clasice, 11 (7,6%). Discomfortul persistent a fost caracterizat drept mediu şi a fost înregistrat la 3 (4,1%) cazuri în lotul Lichtenstein şi la 5 (3,5%) pacienți, la lotul cu intervenții clasice. De asemenea, s-a urmărit prezența sau absența atrofiei testiculare de partea operată.

Recurența a fost definită ca prezența protruziei de partea operată sau apariția ei la efectuarea unei manevre Valsalva şi a fost înregistrată în 17 (11,8%) cazuri din lotul pacienților operați prin tehnici clasice şi nici una în lotul operat prin tehnica Lichtenstein. Recurența a apărut la 4 cazuri de hernie directă, 3 cazuri de hernie mixtă şi 10 cazuri de hernie indirectă (fig. 8).

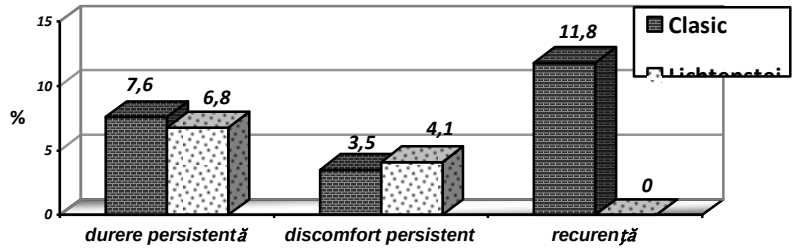

Fig. 8. Distribuția cazurilor în funcție de evoluție

DISCUȚII

Datele din literatura (7, 8) relevă o incidență a recurenței herniare după intervențiile chirurgicale clasice de 12–18%, valori care contrastează cu cele ale operației Lichtenstein de sub 1% (7, 8). Deoarece chirurgia conține şi elemente de manualitate, experiența cu o anumită tehnică poate conduce la rezultate mai bune. Cu toate acestea, tehnica Lichtenstein este o metodă

uşor de reprodus, cu recurenţă a herniei redusă (9, 10). Când o metodă este uşor de învăţat şi reprodus, este atins şi un standard înalt, rezultatele fiind asemănătoare cu cele obţinute într-un centru specializat (10, 11). Spre deosebire de operaţiile tisulare, procedeul Lichtenstein nu are o etapă operatorie de pregătire a canalului inghinal, ci doar una de reconstrucţie (12).

Temerile că materialul prostetic ar favoriza apariţia infecţiilor sau a durerii cronice potoperatorii nu s-au dovedit a fi fondate.

CONCLUZII

Studiul nostru confirmă datele din literatură, care arată că operaţiile tension-free (Licthenstein) sunt uşor reproductibile şi nu necesită o experienţă chirurgicală deosebită. Prin contrast, tehnicile clasice impun o disecţie laborioasă a structurilor anatomice, fiind deseori grevate de complicaţii ca durere cronică persistentă sau recurenţă.

Avantajele tehnicii Lichtenstein sunt simplitatea, reproductibilitatea, eficacitatea, siguranţa şi morbiditatea postoperatorie redusă. De asemenea, metoda prezintă o evoluţie postoperatorie bună, cu control accesibil al durerii şi reinserţie socio-profesională rapidă.

NEW INSIGHTS INTO THE THERAPEUTIC USE OF NITRIC OXIDE-DONATING NON-STEROIDAL ANTI-INFLAMMATORY DRUGS (Abstract): Nitric oxide (NO), a radical with increased reactivity, diffusibility and instability plays an important role in the regulation of a wide range of physiological processes, including cellular immunity, angiogenesis, cardiac function, neurotransmission, and platelet aggregation. Numerous studies in recent decades have demonstrated the benefits and cytoprotective role of nitric oxide in different body systems. A modern experimental and clinical research direction is represented by the development of hybrids containing a NO donor coupled with a classical nonsteroidal anti-inflammatory agent, (NSAID) demonstrating an improved efficacy and tolerability compared to the administration of the drug alone in laboratory animals, in various experimental models. These agents are obtained by the ester linkage of a NO-releasing moiety to a standard NSAID, such as acetylsalicylic acid (NO-aspirin), ibuprofen (NO-ibuprofen), flurbiprofen (NO-flurbiprofen), naproxen (NO-naproxen), diclofenac (NO-diclofenac) and indomethacin (NO-indomethacin). Multiple pharmacological strategies regarding the release of NO from these hybrid NO-releasing compounds provide new insights into the pathogenesis and treatment of various pathological states, such as: inflammatory conditions, hypertension, atherosclerosis, neoplastic disease, degenerative diseases, colitis and bronchial asthma. **Keywords:** NITRIC OXIDE DONORS, NON-STEROIDAL ANTI-INFLAMMATORY DRUGS, CARDIOVASCULAR SYSTEM.

Discovered in 1980 (1), nitric oxide (NO) is a signaling molecule, with an essential role in the mediation of various physiological processes in the body and important functions at the central nervous system (CNS), cardiovascular and immune defense level (2).

The importance of NO, also known as the endothelium-derived relaxing factor, has been studied over the years, being recognized in 1998 (3), when a team of researchers who studied the biological effects of the NO was awarded the Nobel Prize for medicine. NO was identified as a messenger in the CNS, being known as an unstable intracellular factor which mediates the increased levels of cyclic guanosine-3',5'-monophosphate (cGMP) (4).

In the last ten years, intense efforts have been made to obtain NO donors, among

which promising to seem to be the diazeniumdiolates, S-nitrosothiols and hybrid NO donors, such as NO-donating non-steroidal anti-inflammatory drugs (NO-NSAIDs) (5).

Despite the obvious potential of NO, notable progress was not recorded regarding the production of NO donors in the context of the scientific enthusiasm generated by the discovery of this molecule, as an important biological messenger (6).

For the realistic evaluation of NO involvement in the mediation of physiological and pathophysiological processes in the body, the endogenous roles, pharmacodynamic effects of this signaling molecule, and the therapeutic use of NO-donors must be clarified and reconsidered.

Hybrid NO-donating NSAIDs in inflammatory & degenerative diseases

Literature data revealed that the use of hybrid NO-donating NSAIDs intensified the traditional anti-inflammatory activity of the agents in different situations of brain inflammation (7). The delivery of NO-aspirin to the T lymphocytes and monocytes derived from the peripheral blood mononuclear cells causes a transient inhibition of the reduction of cellular ATP and cell respiration, which translates in time, the reversible inhibition of cell proliferation and the secretion of the IL-2, IL-4, IL-5 interleukins and interferon gamma. NO-aspirin induces metabolic hypoxia that inhibits lymphocyte reactivity to co-stimulatory molecules, providing a potential counter mechanism to control the immune system activity (8).

Some authors highlighted that the NO-NSAIDs have additional anti-inflammatory and immunomodulatory properties compared to the standard compounds (9). Moreover, it was discovered that compared to the traditional NSAIDs these hybrid NO-donors are more efficient in the treatment of Alzheimer's disease due to their ability to clear the beta amyloid deposits from the brain of affected laboratory animals (10).

The treatment with NO-flurbiprofen is associated with the decrease of mRNA levels of proinflammatory cytokines, caspase-1 and inducible nitric oxide synthase (iNOS) in blood cells, diminution of encephalitogenic T cells proliferation capacity, reduction of T cells number in the CNS, axonal loss and demyelination. NO-flurbiprofen has been proved to be efficient in reducing the beta amyloid deposition in the brain of transgenic mice with experimentally-induced Alzheimer's disease. Also, it has been demonstrated that only one dose of NO-flurbiprofen lead to the prolonged suppression of brain prostaglandin synthesis, without inducing gastric injury (10).

Experimental researches proved that NO-aspirin prevents the suppression of monocyte tissue factor expression, along with cytokine biosynthesis and inhibition of thromboxane activity. The administration of NO-aspirin in mice exhibits a notable increase in the number of tunnel-positive cells and a decrease in CD45-positive inflammatory cells. The released NO is involved in the reduction of vascular inflammation and promotion of apoptosis during vascular remodeling together with neointimal thickening (11).

Various investigations revealed that NO-donating NSAIDs are very effective in the long-term treatment of chronic inflammatory rheumatic and osteoarticular diseases. A new anti-inflammatory mechanism of NO-aspirin, independent of the cyclo-oxygenase involvement is represented by

the inhibition of the caspase-1 activity. It was demonstrated that the use of NO-aspirin induces the release of intracellular NO and decreases IL-1β and IL-18 synthesis, by inhibiting the activity of caspase-11 (11). Also, NO-naproxen showed the reduction in IL-1β and TNFα plasma levels, and the prevention of T-cell proliferation (5).

Hybrid NO-donating NSAIDs in cardiovascular diseases

Today the role of NO in the cardiovascular system is well known. It was discovered that NO induces vasodilatation through different actions, like initiating the cyclic guanosine monophosphate (cGMP) synthesis from guanylate cyclase in vascular smooth muscle cells, but it also has some favorable effects (antiatherogenic, antiplatelet) by inhibiting inflammation, platelet aggregation, cell proliferation and apoptosis (12). Compared to aspirin, NO-aspirin has more valuable effects on the cardiovascular system, being able to inhibit shear stress-induced platelet activation. NO-aspirin can inhibit the formation of superoxide radical and the expression of nicotinamide adenine dinucleotide phosphate (NADPH) oxidase subunits induced by endoxin and cytokines in the vascular wall (13).

Napoli *et al.* (14), in clinical trials, have reported that NO-aspirin could be beneficial for the prevention of restenosis after percutaneous intervention, with significant antihypertensive effects. It was discovered that unlike classic aspirin, NO-aspirin reduces the severe restenosis in mice with experimentally-induced hypercholesterolemia (15). This hybrid agent combines in a single molecule, the classic aspirin, the most used drug in cardiovascular diseases, and the nitric oxide, the most important signaling molecule in human vessels. A comparable effect was also observed in rats with vascular injury and restenosis after NO-flurbiprofen use, its administration significantly reducing the neointimal proliferation after percutaneous coronary angioplasty (16).

NO-aspirin reduces ischemia in the rabbit heart, while the traditional aspirin aggravates the resulting myocardial dysfunction. Some results show that NO-aspirin also has vasodilatory activity in the venous grafts used for coronary artery bypass grafting, this effect not being modified under the action of vascular wall functional abnormalities, as in diabetes mellitus (17). The use of NO-aspirin proved to be beneficial for the prevention of blood clot formation and diminution of cardiovascular side effects (stroke, myocardial infarction), and a possible valuable role in non-alcoholic fatty liver disease (18). Reparative angiogenesis and prevention of apoptosis and oxidative stress are stimulated by the treatment with NO-aspirin, thus reducing the consequences of arterial occlusion.

It is also involved in the diminution of sympathetically-mediated vasoconstriction and lowering of blood pressure in hypertensive rats (19). Moreover, NO-aspirin considerably reduces the plasma LDL levels, decreases the atherosclerotic processes in the arterial wall and the local oxidative stress in the hypercholesterolemic mice (15).

Various other studies revealed the cardioprotective effects of NO-aspirin, probably mediated by NO donation, thus suggesting that this NO-donor agent could be beneficial in the treatment of infarction and myocardial ischemia (20). Similar as other NO-donating NSAIDs, it does not deter-

mine substantial changes in arterial blood pressure and heart rate after intravenous, intraperitoneal or oral administration in rats.

NO-donating NSAIDs are significantly less potent vasorelaxants than the classic nitro vasodilators (5). The inability of NO-NSAIDs to reduce systemic blood pressure in normotensive rats may be explained by the absence of the vasorelaxant effect of these compounds *in vitro*. Other experimental researches demonstrated that NO-naproxen considerably decreases hypertension induced by the obstruction of one renal artery (21).

Aspirin, which exerts its antiplatelet effects by the irreversible inhibition of cyclooxygenase 1 (COX-1), is currently used for the prevention and treatment of cardiovascular diseases. Experimental researches showed that NO-aspirin induces more platelet function inhibition, compared to traditional aspirin, both *in vitro* and *in vivo*, in rats and in humans (22). Also, NO-aspirin was more effective than aspirin in reducing the plasma epinephrine level and the collagen formation. NO-aspirin proved to be efficient against mechanically-induced thrombus formation, and vasodilatation mediated by the release of NO may probably contribute to its protective effect on the vessels (23).

It was demonstrated that NO-aspirin has an improved antiplatelet activity, and, it can protect the gastrointestinal tract exposed to other injurious agents (24). The inhibitory activity of NO-aspirin on leukocyte adherence to the vascular endothelium contributes to its antiplatelet activity. NO-aspirin prevents platelet aggregation mediated by the arachidonic acid and inhibits serum thromboxane biosynthesis. Moreover, it was shown that NO-aspirin does not inhibit the synthesis of platelet thromboxane or gastric prostaglandins, but releases NO and increases the cGMP levels in platelets, when incubated in their presence (2, 25).

CONCLUSIONS

Researching the literature data, we highlighted that NO represents an important molecule that plays a key role in signaling processes with extensive cardiovascular, nervous and immune system functions. In what concerns one new modern pharmacologic research field, we noticed that a valuable therapeutic direction is the development of hybrid NO-donating NSAIDs that have demonstrated efficacy in inflammatory, degenerative and cardiovascular diseases, in both experimental studies and clinical trials.

ASPECTE PARTICULARE CLINICO-IMAGISTICE ÎNTÂLNITE ÎN TROMBOFLEBITA SINUSULUI LATERAL

N.S. Axinte[1], V. Costinescu[2], D. Palade[2]
1. Doctorand al Universității de Medicină şi Farmacie „Grigore T. Popa" - Iaşi
Universitatea de Medicină şi Farmacie „Grigore T. Popa" - Iaşi
Facultatea de Medicină
2. Disciplina de O.R.L.

CLINICAL AND IMAGISTIC PARTICULAR ASPECTS IN LATERAL SINUS THROMBOPHLEBITIS (Abstract) Aim: This article focuses on the lateral sinus thrombophlebitis, which is a serious complication of the supurated otopathies**. Material and methods**: It is based on a study of a significant number of both exo- and endocranial complications treated in the the "Sf Spiridon" Hospital- ORL department and at the "Prof. dr. N. Oblu"- Neurosurgery department (57 out of 251 cases admitted in the past 5 years). **Results**: Among the 57 cases, there were 8 lateral sinus thrombophlebitis, as well as 6 cases where meningitis coexisted with other endocranial complications, such as lateral sinus thrombophlebitis or brain abscess. The article contains details about some cases with special problems of diagnostic and treatment. **Conclusions**: The symptoms of the presented cases are completely different from the common symptomatology. However, the diagnostic of such cases is possible due to the modern imaging methods as well. The lateral sinus thrombophlebitis is usually determined by different causes, one of them being the misuse of the antibiotics(class and daily/total dose).When endocranial complications occur the symptoms of the meningitis are masking the symptoms of other complications. Even if the CT scan or MRI exams performed right on the patient's admission show no other complications, the patient should be followed for a period of 15 up to 30 days after the treatment of the meningitis, by repeating imaging tests to identify a possible complication. **Key words**: LATERAL SINUS THROMBOPHLEBITIS, COMPLETE IMAGING EXAM, INFECTION, SURGICAL ABLATION

Complicaţiile extra şi endocraniene ale otitelor medii supurate şi ale otomastoiditelor înregistrează o incidenţă cu valori crescute în România, îndeosebi în Moldova.

În ţările dezvoltate, incidenţa acestor complicaţii este evaluată între 0,5 - 7 %, (1, 2, 3, 4), pentru ca în România, în special în judeţele nord-estice, să reprezinte peste 20% din cazurile de otite medii supurate şi de otomastoidite. În lucrare se încearcă o analiză asupra cauzelor şi explicaţiilor care determină existenţa acestei incidenţe crescute, prezentând în detaliu, unele cazuri cu anumite particularităţi clinice şi o evoluţie diferită faţă de tabloul clasic.

Ne vom referi la cazuri de tromboză a sinusului lateral produsă datorită unei eroziuni osoase de vecinătate prin colesteatom, osteită şi granulaţii care întreţin un abces perisinusal. Abcesul la rândul său a determinat un agregat fibrinos de celule sangvine şi plachete în peretele sinusal, realizând un trombus parietal. Acest trombus se infectează ulterior, creşte în volum

şi determină obliterarea sinusului (1,2,3,4). Clasic, tabloul clinic al tromboflebitei se manifestă prin:

• instalarea unui sindrom infecţios sever, cu creşterea considerabilă a numărului leucocitelor, febră ridicată 39,5 – 40 0 C, frison şi un sindrom de iritaţie meningoencefalică cu tulburări ale vigilenţei dacă coexistă cu o meningită sau un abces cerebral;

• starea generală foarte alterată; lipsa sindromului meningeal franc;

• apariţia frecventă a unor simptome evocatorii: otalgia, cefaleea şi edemul mastoidian (semnul Griessinger) care traduc tromboza septică a venei emisare mastoidiene;

• atingerea frecventă a nervilor VI şi VII sau sindromul de gaură ruptă posterioară (IX,X,XI).

Examenul CT, RMN şi uneori incidenţa clasică Schuller pot evidenţia o opacitate a sinusului lateral şi absenţa opacităţii venoase dupa injectarea substanţei de contrast (semnul Delta). Numai examenul angioRMN poate confirma cu exactitate ocluzia venoasă. EcoDoppler-ul îşi are utilitatea în cazul în care coexistă tromboza venei jugulare, mai ales în urmărirea evolutivă a tromboflebitei sinusului lateral.

Dulli et al. (5), Ram et al. (6) consideră că tromboflebita sinusului lateral s-ar putea datora unei stări pretrombotice, de obicei, congenitale sau acumulate în timpul sarcinii, a unei afecţiuni hematologice sau sistemice postmedicamentoase cum sunt rezistenţa la proteina C reactivă care duce la fenomene de mutaţie a factorului V Leiden. De asemenea, proteina S, un factor antitrombinic III, precum şi sindromul primitiv al anticorpilor antifosfolipidici pot determina o maladie mieloproliferativă cu sindrom nefrotic, hemoglobinurie paroxistică nocturnă, maladia lui Behcet la fel ca şi dozele excesive de corticoizi.

Evoluţia ulterioară a unei tromboflebite a sinusului lateral, netratată la timp, duce la riscuri vitale majore cum este embolia pulmonară septică (sdr. Lemierre) cu Fusobacterium necrophorum (Hughes et al. (7), Ieven et al. (8)), extensia la alte sinusuri venoase din duramater şi ridicarea presiunii intracraniene, septicemie sau septicopioemie.

După 1990, urmare a introducerii pe scară largă a antibioticelor cu spectru larg şi în România, au început să apară forme clinice fruste de otite medii acute, otite medii cronice reacutizate, folosindu-se termenul de mastoidite „decapitate”, urmarea probabilă a utilizării unor antibiotice necorespunzătoare afecţiunii şi a unor doze insuficiente.

În cazul observaţiilor noastre a rezultat modificarea florei microbiene, iar durata tratamentului a fost insuficientă, numeroşi pacienţi au beneficiat de un tratament incomplet pe o durată mai redusă de 7-14 zile şi în absenţa controlului periodic al medicului practician (9,10).

MATERIAL ŞI METODE

În studiu au fost incluse 57 de cazuri de intervenţii chirurgicale la nivel otomastoidian efectuate în ultimii 5 ani în clinica ORL din Spitalul Clinic de Urgenţe „Sf. Spiridon” din Iaşi. Informaţiile au fost acumulate printr-o fişă de anchetă, incluzând datele de caracterizare a lotului de studiu şi cele obţinute din analiza rapoartelor statistice oficiale. Prelucrarea şi interpretarea rezultatelor s-a realizat prin metode clinico-epidemiologice şi statistico-matematice.

REZULTATE ŞI DISCUŢII

Prezentăm cazul unui copil de 10 ani care a beneficiat de un tratament pentru otită medie acută, timp de 7 zile, şi care în

final a acuzat deficit auditiv, hemicranie dreaptă şi discretă otalgie periodică pe o stare discretă de obnubilare fără simptomatologie caracteristică tromboflebitei.

Examenul CT a arătat o îngroşare a peretelui sinusului lateral drept, însă radiografia clasică Schuller şi angioRMN-ul au evidenţiat un posibil proces de tromboflebită. Descoperirea intraoperatorie a sinusului lateral şi puncţionarea sa au demonstrat existenţa unui proces gleros perisinusal şi tromboza parţială a sinusului. La examenele imagistice efectuate nu s-a constatat voal mastoidian şi nici liză a pereţilor celulelor mastoidiene.

Particularitatea acestui caz constă în aceea că nu a prezentat niciunul din simptomele clasice, însă examenele imagistice complementare au putut să inducă posibilitatea existenţei unei tromboflebite a sinusului lateral.

Dacă nu s-ar fi intervenit chirurgical, am fi putut asista ulterior la apariţia altor complicaţii endocraniene cum ar fi abcesul cerebelos, cerebral sau meningita, motiv pentru care se confirmă faptul că focarul infecţios endocranian nu poate fi neglijat în cazul existenţei unei infecţii otomastoidiene.

Un alt caz particular îl constituie şi un bolnav în vârstă de 24 ani cu aticită colesteatomatoasă care s-a prezentat cu o discretă hemicranie, febră (39-40 ^{0}C), frison, 10500 leucocite, cu predominanţa neutrofilelor, iar palparea venei jugulare a relevat o discretă sensibilitate în jumătatea superioară a regiunii cervicale.

Practicarea intervenţiei chirurgicale, cu descoperirea sinusului lateral, a relevat prezenţa unei tromboflebite cu obstrucţia completă a sinusului. După secţionarea sinusului lateral şi eliminarea trombusului s-a reluat circulaţia venoasă în amonte şi în aval.

În evoluţia ulterioară, nivelul febrei a scăzut, dar frisonul a continuat să persiste, iar febra a devenit de tip supurativ (38,5 ^{0} C seara cu 37 ^{0} C dimineaţa).

Cu asemenea evoluţie, s-a suspicionat persistenţa unui proces tromboembolic la nivelul venei jugulare încât s-a decis intervenţia chirurgicală pe vena jugulară în vederea ligaturării acesteia şi a afluenţilor pentru a preîntâmpina o invazie a trombilor în alte teritorii cu apariţia unei embolii pulmonare, septicemii sau septicopioemii.

După ligatura venei jugulare interne a persistat febra de tip supurativ şi după încă 3 zile s-a decis excluderea venei jugulare interne şi a golfului jugularei (intervenţia Grunert), după care evoluţia pacientului a fost favorabilă.

În perioada 2006-2010 au fost asistate în clinica ORL 251 de cazuri de otomastoidite dintre care 57 (22,7%) cu complicaţii (fig. 1).

Din totalul de 251 de cazuri, 9 (3,6%) cazuri au prezentat meningită, iar 6 (2,4%) cazuri au prezentat concomitent tromboflebită de sinus lateral, abces cerebral sau cerebelos. Din aceste 6 cazuri, 3 au fost diagnosticate imagistic după vindecarea meningitei încât, dacă pacienţii ar fi fost externaţi, am fi putut asista ulterior la un aşa zis „deces de cauză necunoscută”.

Este posibil ca la examenul imagistic iniţial când s-a prezentat bolnavul să nu fie descoperită complicaţia endocraniană şi ea să fie decelată ulterior la un interval de 10 - 20 zile datorită faptului că aceasta era în evoluţie şi nu evidenţia prezenţa unor semne certe cum ar fi opacitatea sinusului lateral sau capsula de abces cerebral sau cerebelos.

Al treilea caz este al unui copil de 6 ani care s-a prezentat la internare prin transfer de la Spitalul de Neurochirurgie unde i se evacuase un abces extradural. În clinica O.R.L. a Spitalului „Sf. Spiridon” s-a prac-

ticat evacuarea unui alt abces extradural, existent în preajma focarului infecțios otomastoidian şi eradicarea acestui focar. După practicarea intervenției chirurgicale asupra blocului otomastoidian cu eliminarea focarului infecțios şi drenarea abcesului extradural, bolnavul a prezentat o stare generală bună.

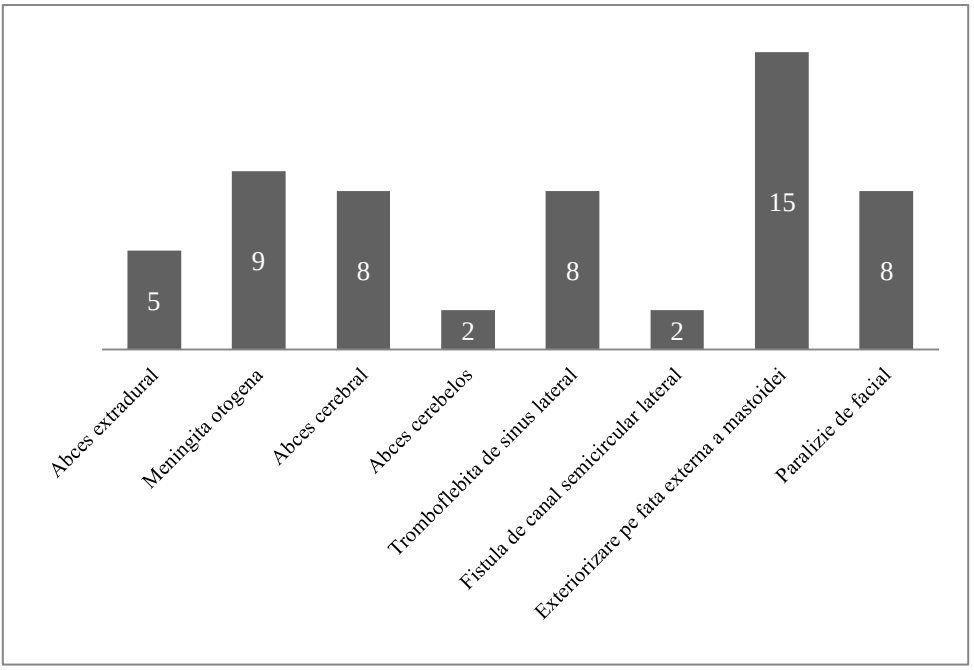

Fig. 1. Repartiția pe tipuri de complicații a lotului de 57 de pacienți

După aproximativ 8-10 zile de la ultima intervenție chirurgicală, pacientul a prezentat o stare de afectare intelectuală cu diminuarea atenției, un grad de dislalie, fapt ce a sugerat posibila existență a unui abces cerebral în evoluție.

Examenul CT a relevat prezența unui abces cerebral, cu dimensiuni de 5-6 cm, care a fost drenat chirurgical la Spitalul de Neurochirurgie şi urmat de o evoluție favorabilă.

Evaluarea evoluției cazurilor discutate a permis a se aprecia că tratamentul tromboflebitei sinusului lateral include pe lângă eradicarea chirurgicală a focarului infecțios otomastoidian şi terapia cu antibiotice asociată cu antiinflamatorii, anticoagulante (11,12).

CONCLUZII

Tromboflebita de sinus lateral rămâne o complicație cu o evoluție posibil severă a otitei medii supurate şi otomastoiditei, cu implicații deosebite în cazul formelor clinice cu simptomatologie frustă.

Examenele imagistice incluzând CT, IRM, angioRMN sunt de un real folos în stabilirea diagnosticului de tromboflebită, mai ales în cazurile cu simptomatologie clinică frustă.

În cazul existenței unui focar supurativ al substanței cerebrale sau cerebeloase, după drenarea acesteia va fi obligatorie şi eliminarea focarului infecțios otomastoidian.

În cazul meningitei otogene rebele la

tratament, coexistente cu alte procese supurative endocraniene, intervenția asupra blocului otomastoidian devine obligatorie pentru a înlătura focarul infecțios otomastoidian care favorizează apariția şi persistența complicațiilor. Concomitent, se impune reevaluarea eficienței antibioterapiei în relație cu rezistența florei microbiene implicate pentru a asigura eficiența tratamentului.

În unele cazuri se impune ligaturarea venei jugulare interne pentru a preveni apariția complicațiilor de tip septic.

SURGICAL REOPERATIONS FOR POSTOPERATIVE PERITONITIS (Abstract): In our clinical study postoperative peritonitis represent 17.01% by operations for neglected peritonitis. The other abdominal complications are eviscerations, postoperative oclusions and residual abscesses. **Material and method:** We have to analize the incidence, etiology, diagnosis and surgical management of 25 cases by postoperative peritonitis which appears after operations of 147 cases by neglected peritonitis. The semiology of a postoperative peritonitis it is easy to recognize in young pacients with reactions which appear in a few days after operations : pain localised to the abdominal area well localised in an area in which palpation show contraction. In a few hours the pain became flow. It appears fever,nausea,vommiting and all the clinical signs of peritonitis.**Results:** The highest prevalence of postoperative peritonitis for which we perform reoperations it appears after appendectomy in 18 cases with fatality 11.11%; next are coming reoperations on stomac and duodenum 4 cases with rate of fatality by 50%, reoperations on small bowell in 2 cases with fatality by 50% and reoperations of big bowell (1 case). On our series of postoperative peritonitis we have a global rate of fatality by 20% from all cases. We have considered this level well in comparison with the dates from another similar experience which show us a rate of fatality which are gone until 90%. Our media of reoperations were about three operations on each cases. If we compare with first operation for neglected peritonitis we have observe that in reoperations we change our plans in the way of making faster minimum necesary because of high risk to dead of this cases. **Conclusions**: Clinical diagnosis by postoperative peritonitis is difficult to establish and only folow up very care clinical signs of this cases beneath laboratory findings (leucogram, uree, ionogram) and with radiological examination (CT) can tell us about postoperative peritonitis.**Key words**: REOPERATIONS, POSTOPERATIVE PERITONITIS, NEGLECTED PERITONITIS.

Semiologia unei peritonite postoperatorii poate fi uneori edificatoare în special la pacienții tineri care au o bună reactivitate: la câteva zile după intervenție bolnavul acuză o durere violentă în abdomen, inițial bine localizată într-o zonă în care palparea constată apărare sau contractură. În câteva ore durerea şi contractura difuzează, apar febra, frisonul, vărsăturile şi toate semnele clinice şi biologice care întregesc tabloul clinic obişnuit al peritonitelor.

De cele mai multe ori aspectul clinic al peritonitelor postoperatorii diferă însă în mod esențial de cel cunoscut, datorită caracterului atenuat atipic sau chiar prin lipsa semnelor obişnuite care devin inaparente

datorită şi tratamentului la care sunt supuşi bolnavii după operaţie.

Peritonita postoperatorie este o formă clinică specială nu numai prin cauză dar şi prin aspectele semiologice deosebite care pot ridica probleme delicate de diagnostic. Etiologic contaminarea se poate realiza în timpul operaţiei prin diseminarea unei colecţii purulente preexistente sau prin răspândirea intraperitoneală a conţinutului septic al unui organ cavitar. Mai des însă momentul infecţiei este postoperator prin dehiscenţa mică sau largă a unei suturi sau anastomoze de organ cavitar care lasă să se scurgă un conţinut septic în peritoneu.

MATERIAL ŞI METODĂ

Pe cazuistica studiată peritonitele postoperatorii reprezintă 17,01% din totalul cazurilor operate pentru peritonite neglijate. Celelalte complicaţii abdominale sunt reprezentate de eviscerația postoperatorie (3,40%), ocluzia intestinală postoperatorie (6,80%) şi abcesele reziduale (10,88%).

Vom analiza mai detaliat incidenţa, etiologia, diagnosticul şi atitudinea terapeutică chirurgicală în cele 25 de cazuri de peritonite postoperatorii survenite după operarea unui număr de 147 de cazuri de peritonite neglijate. Semiologia unei peritonite postoperatorii poate fi uneori clară în special la pacienţii tineri care au o bună reactivitate: la câteva zile după operaţie bolnavul acuză o durere violentă în abdomen, iniţial bine localizată într-o zonă în care palparea constată apărare sau contractură. În câteva ore durerea şi contractura difuzează, apar febra, frisonul, vărsăturile şi toate semnele clinice şi biologice care întregesc tabloul clinic obişnuit al peritonitelor. Pe toată cazuistica studiată am înregistrat următoarele complicaţii survenite postoperator (tab. I).

Se observă cum complicaţiile generale survin în 23,80% din cazuri şi sunt reprezentate de complicaţiile cardiovasculare, pulmonare şi renale. În 40,82% din cazuri apar complicaţiile locale reprezentate de supuraţia plăgii.

TABELUL I

Complicaţii survenite postoperator

	Complicatii survenite	Nr. cazuri	%
1	Supuraţia plagii	60	40,82
2	Eviscerația postoperatorie	5	3,40
3	Abcese reziduale	16	10,88
4	Ocluzie intestinală postoperatorie	10	6,80
5	Peritonita postoperatorie	25	17,01
6	Complicaţii pulmonare	12	8,16
7	Complicaţii cardiovasculare	8	5,44
8	Complicaţii renale	15	10,20

Peritonita postoperatorie este o formă clinică specială nu numai prin cauză dar şi prin aspectele semiologice deosebite care pot ridica probleme delicate de diagnostic (1). Etiologic contaminarea se poate realiza în timpul operaţiei prin diseminarea largă a unei colecţii purulente preexistente sau prin răspândirea intraperitoneală a conţinutului septic al unui organ cavitar. Mai des însă momentul infecţiei este postoperator prin dehiscenţa mică sau largă a unei suturi sau anastomoze de organ cavitar care lasă să se

scurgă în peritoneu un conținut septic (2). Cazuistica noastră cuprinde un număr de 7 cazuri de peritonite produse prin dehiscențe ale suturilor sau anastomozelor efectuate (tab. II) în care am practicat exteriorizarea de anastomoză dezunită în 3 cazuri şi sutură secundară cu colostomie de protecție în 4 cazuri.

TABELUL II

Tratament chirurgical – Intervenția chirurgicală principală în peritonita neglijată datorată dehiscențelor anastomotice

Tip de intervenție chirurgicală	Nr. cazuri	%
Exteriorizare de anastomoză dezunită	3	42,86
Sutura secundară cu colostomie de protecție	4	57,14
Drenaj	7	100,00
Refacerea peretelui abdominal în plan total	7	100,00

TABELUL III

Semne clinice în peritonitele postoperatorii

Semne clinice	Nr. cazuri	%
Dureri abdominale	19	76
Meteorism abdominal	12	48
Apărare musculară	10	40
Contractură abdominală	6	24
Oprirea tranzitului abdominal	7	28
Fund de sac Douglas destins	14	56
Vărsături	11	44
Lichid fetid exteriorizat prin drenuri şi plagă	6	24
Sughiț	2	8
Limba uscată	18	72
Facies peritoneal	7	28
Oligoanurie	16	64
Tahicardie	18	72
Frisoane	19	76
Agitație psihomotorie	10	40
Febră	21	84

Cazurile cele mai frecvente au fost cele ale peritonitelor postoperatorii care au survenit fără a avea legătură cu motivul şi sediul primei operații fiind consecința unor leziuni determinate de alți factori.

Durerea abdominală apărută după un interval liber postoperator a fost primul semn revelator, dar numai în 19 cazuri, adică 76% din numărul total de cazuri. Deoarece peritonita postoperatorie presupune o infecție, febra a fost un semn constant, apărând în 21 de cazuri, adică 84% din numărul total de cazuri. La fel, tahicardia a fost un semn constant, apărând în 18 cazuri, adică 72% din numărul total de cazuri, iar frisoanele au fost prezente în 19 cazuri, adică

76% din numărul total de cazuri.

Dar ceea ce a atras de la început atenția la toți bolnavii, determinând recurgerea la investigații clinice, radiologice şi de laborator, a fost alterarea bruscă în postoperator a stării generale (3).

Controlul plăgii pe unde se scurg lichide septice şi repermeabilizarea tuburilor de dren a înlesnit diagnosticul în 24% din cazuri. Un foarte important semn clinic a fost bombarea şi „țipătul Douglasului"(4), prezent în 14 cazuri, adică 56% din numărul total de cazuri.

Din punct de vedere al grupelor de vârstă (tab. IV), s-a constatat o frecvența ridicată a peritonitelor postoperatorii la grupa de vârstă 50-59 ani.

Cea mai mică frecvență a peritonitelor postoperatorii s-a înregistrat la grupa de vârstă 70 ani şi peste (un caz, respectiv 4%).

TABELUL IV

Repartiția peritonitelor postoperatorii pe grupe de vârstă

	Nr. cazuri	**%**
10 - 19 ani	2	8
20 - 29 ani	3	12
30 - 39 ani	4	16
40 - 49 ani	3	12
50 - 59 ani	8	32
60 - 69 ani	4	16
70 ani şi peste	1	4
TOTAL	**25**	**100**

Prevalența cea mai mare a peritonitelor postoperatorii am înregistrat-o după operațiile pe apendice, 18 cazuri, cu o rată a fatalității de 11,11%; urmează intervențiile pe stomac şi duoden, 4 cazuri, cu o rată de fatalitate de 50%, intervențiile pe intestinul subțire, 2 cazuri, cu o rată a fatalitate tot de 50% şi intervenția pe colon (un caz), cu evoluție favorabilă.

Pe lotul nostru de peritonite postoperatorii am înregistrat o rată globală de fatalitate de 20% din totalul cazurilor de îmbolnăvire. Acest indice este considerat bun, în comparație cu datele din literatura de specialitate, care indică o fatalitate de până la 90% (5). În aceste cazuri de peritonite postoperatorii am practicat următoarele reintervenții chirurgicale (tab. V).

TABELUL V

Reintervenții chirurgicale în peritonitele postoperatorii

Pe stomac şi duoden - sutura secundară
- excizie - sutură
- rezecție gastrică cu anastomoză tip Pèan la cazurile cu sutură nereuşită prima dată
- drenaj simplu în dreptul dehiscenței
Pe intestinul subțire
- enterectomie complementară cu anastomoză termino-terminală
- exteriorizarea anastomozei dezunite
Pe colon - exteriorizare de anastomoză dezunită
- sutură secundară cu colostomie de protecție
Eviscerații - refacerea peretelui abdominal cu inele Georgescu

La 4 pacienţi din totalul de 25 s-a reintervenit de mai multe ori. Un număr de doi bolnavi dintre aceştia (50%) au decedat. Media reintervenţiilor a fost de trei. Comparativ cu prima intervenţie efectuată pentru peritonită neglijată se observă la reintervenţii o schimbare uşoară a conduitei chirurgicale în sensul simplificării operaţiei datorită gravităţii cazului (6). Astfel se observă că unul din principiul de bază al reintervenţiilor chirurgicale este acela de a efectua un act chirurgical minim,cât mai simplu pentru a uşura şi a face suportabil un act chirurgical repetat, cu o nouă anestezie generală pe un pacient suferind. Principiul de bază al reintervenţiilor este simplitatea gestului chirurgical de rezolvare a cauzei care a produs peritonita postoperatorie (7). Existenţa de peritonite postapendicectomie atrage atenţia că şi această „operaţie banală" trebuie executată de chirurgi experimentaţi, care ştiu să prevadă şi să ocolească cauzele acestei complicaţii. Pacienţii care au dezvoltat insuficienţă renală şi şoc toxicoseptic au decedat (8). Media reintervenţiilor în aceste cazuri a fost de trei.

Pe stomac şi duoden reintervenţiile au constat în suturi secundare, excizii şi sutură, rezecţie gastroduodenală cu gastroduodenoanastomoză la sutură nereuşită, conversie gastrojejunală după dezunire de anastomoză, sau simplu drenaj lângă dehiscenţă (9).

Pe intestinul subţire reintervenţiile au constat în enterectomie complementară cu rezecţia porţiunii compromise cu anastomoză entero-enterală termino-terminală şi numai într-un caz o exteriorizare de anastomoză dezunită (10). Am constatat că cel mai bun procedeu de refacere a circuitului digestiv după o peritonită postoperatorie datorată unei dehiscenţe de anastomoză termino-terminală de intestin subţire este rezecţia până în ţesut sănătos cu enteroanastomoză terminoterminală şi numai la nevoie se recurge la ileostomie de protecţie (11).

Pe colon reintervenţiile au constat în exteriorizare de anastomoză dehiscentă sau sutură secundară cu colostomie în amonte. De asemenea în literatura de specialitate se menţionează o reducere a dehiscenţelor suturilor colice dacă se practică în amonte o colostomie de protecţie (12).

Nu am practicat cecostomie.

Întotdeauna după o incizie tip MacBurney am ales calea de abord mediană ombilicopubiană şi nu o prelungire a inciziei iniţiale. După laparotomie urmează descoperirea şi evaluarea colecţiilor peritoneale.

În urma desfiinţării cavităţilor formate prin secţionarea bridelor am toaletat cavitatea peritoneală cu ser fiziologic cald şi betadină şi cu îndepărtarea falselor membrane de pe seroase (13).

După realizarea drenajului decliv am terminat intervenţia chirurgicală prin refacerea peretelui abdominal în plan total. În câteva cazuri am utilizat inelele Georgescu cu bune rezultate. La fel am procedat şi în cazurile de eviscerație postoperatorie prin închiderea peretelui abdominal cu aceste inele. Pe lângă simplitatea gesturilor am căutat ca timpul operaţiei de reintervenţie să fie cât mai mic (14). Am combinat simplitatea cu eficienţa.

Nu am folosit niciodată metoda deschisă, a laparostomiei şi nici a lavajului drenaj postoperator cu diferite soluţii deoarece consider că o toaletă bună efectuată intraoperator şi un drenaj eficient ajută mai bine peritoneul să se apere. În toate aceste cazuri antibioterapia a fost condusă conform rezultatelor antibiogramei. În perioada postoperatorie am tratat aceşti pacienţi ca fiind multişocaţi (şoc operator, toxicosep-

tic) şi cu multiple disfuncţii ale organelor (MSOF).

DISCUȚII

Prevalența peritonitelor postoperatorii este dificil de apreciat datorită condițiilor de apariție la un bolnav deja operat. Peritonitele postoperatorii au o evoluție gravă şi imprevizibilă (11,14).

Dificultatea stabilirii diagnosticului este datorată şi modificărilor tabloului clinic prin folosirea antibioticelor, analgeticelor şi existența aspirației nasogastrice; tabloul clinic poate simula alte afecțiuni precum infarctul de miocard, embolia pulmonară sau septicemia.

Creşterea duratei spitalizării preoperatorii creşte riscul colonizării bolnavului cu germeni rezistenți ceea ce face ca antibioterapia să fie ineficace. Alteori, pregătirea preoperatorie a bolnavului este insuficientă sau se referă la pregătirea preoperatorie mecanică şi chimică a colonului sau la lipsa eradicării unui focar infecțios ce nu are legătură cu boala pentru care se intervine chirurgical.

Un alt factor de gravitate a bolii este durata actului operator, riscul de deces dublându-se cu trecerea fiecărei ore (12, 14).

Cauzele peritonitelor postoperatorii sunt diverse: dezunirea anastomozelor digestive efectuate pe un segment intestinal inflamat, prost vascularizat sau deperitonizat.

După anastomozele colorectale prevalența variază între 1-10% fără diferențe semnificative între anastomozele efectuate prin sutură sau mecanice (13, 14).

Anastomozele gastrojejunale sau esojejunale se pot complica cu peritonite postoperatorii cu o frecvență mai mare în chirurgia oncologică.

Toaleta peritoneală incompletă sau drenajul ineficient pot cauza peritonite postoperatorii.

O altă cauză o constituie contaminarea directă a peritoneului în cursul laparotomiei fie din afară când nu se respectă regulile de asepsie, dar mai frecvent din interior prin manevrele efectuate pe organe inflamate şi cu conținut septic.

Peritonitele postoperatorii se întâlnesc la 4-6% dintre apendicectomizați, iar 43% dintre aceştia nu au prezentat inițial o apendicită complicată cu peritonită neglijată (14). În cazuistica noastră am înregistrat o prevalență similară.

De asemenea peritonitele postoperatorii pot apărea datorită unor leziuni ignorate în timpul primei intervenții sau incorect apreciate ca potențial evolutiv sau pot fi datorate unor leziuni provocate şi nerecunoscute cum se întâmplă în timpul eliberării aderențelor, sau pot fi datorate infectării secundare a revărsatelor peritoneale de la alte infecții localizate.

Alte cauze de producerea peritonitelor postoperatorii pot fi reprezentate de deraparea ligaturilor cu hemoragie secundară şi suprainfecție, lezări accidentale nerecunoscute cum sunt cele întâlnite în chirurgia laparoscopică.

CONCLUZII

Peritonitele postoperatorii prezintă o gravitate deosebită cu toate progresele înregistrate atât în diagnostic cât şi ca tratament.

Diagnosticul afecțiunii este dificil de stabilit fiind pus cu întârziere ceea ce atrage după sine pierderea momentului operator optim.

Peritonita postoperatorie necesită un tratament complex medico-chirurgical.

Baza tratamentului este reintervenția chirurgicală. Se impune toaletizarea cavității peritoneale cu îndepărtarea colecțiilor

purulente, a falselor membrane şi un lavaj intraoperator bun al cavității.

Tratamentul chirurgical în reintervenţii trebuie să fie simplu şi adecvat leziunilor găsite intraoperator, completat cu un tratament de reechilibrare hidro-electrolitică, de corijare a dezechilibrelor şi de combatere a infecției.

TOXIC CAUSE FEBRILE NEUTROPENIA (Abstract): Agranulocytosis is an acute disease with severe leucopenia, especially with low neutrophils, elements with an essential role in the organism's defense. It is more frequent at adult age (between 30 to 70 years of age) especially in women. We present the case of a 84 years old patient that, following passive exposure to pesticides, develops a severe neutropenia with a fast response to the administration of Methylprednisolone and granulocyte colony-stimulating factor (G-CSF – Filgrastim 48MIU/0.8mL/day, for three days). The diagnostic certainty was set by the bone marrow puncture which excluded a possible aleukemic acute leukemia or a myelodysplastic syndrome. **Key words:** TOXIC AGRANULOCYTOSIS, PASSIVE EXPOSURE TO PESTICIDES, FAST RESPONSE TO FILGRASTIM

Leucocitele sunt elemente nucleate, diferite morfologic şi funcţional care circulă împreună în sângele periferic şi participă la procesul de apărare a organismului.

Granulocitopoeza are loc în măduva osoasă din celulele reticulare imature, celule "stem", trecând prin următoarele etape: mieloblast, promielocit, mielocit, metamielocit nesegmentat, ajungându-se la celule mature, segmentate cu nucleu polilobat şi granulaţie în citoplasmă.

Agranulocitoza desemnează o stare de scădere critică a leucocitelor, în special a neutrofilelor, ce poate apărea ca reacţie adversă la diverse clase de medicamente, de la banalele analgezice până la chimioterapice şi medicaţia SNC. Aceasta se poate instala prin mecanism farmacodinamic secundar, mecanism toxic sau imunoalergic, se manifestă dramatic şi poate pune viaţa în pericol.

Agranulocitoza este o stare acută, ce presupune o leucopenie severă, în special de scădere a neutrofilelor, o clasă importantă a celulelor cu rol esenţial în apărarea organismului. În agranulocitoză, concentraţia granulocitelor (neutrofile, bazofile şi eozinofile) scade sub 100 celule/mm³, ceea ce reprezintă doar 5% din valoarea normală.

Diagnosticarea agranulocitozei se face după numărarea elementelor figurate sangvine, atunci când numărul neutrofilelor este sub 500/mm³ putând ajunge chiar şi la 0 celule/mm³. Celelalte elemente figurate sunt, în general, în parametri normali.

Pentru a pune diagnosticul de agranulocitoză trebuie însă înlăturate alte posibile afecţiuni, precum mielodisplazia sau leucemia acută forma aleucemică.

PREZENTARE DE CAZ

Prezentăm cazul unui pacient de 84 ani care se adresează iniţial Spitalului de Neurologie Iaşi unde se află în evidenţă datorită unui accident ischemic tranzitor suferit în martie 2009.

Motivele internării: disfagie pentru lichide şi solide, cefalee importantă, febră (39ºC), astenie fizică marcată.

Datorită decelării unui număr scăzut de globule albe (GA= 1000/mm³), fără a se obiectiva o acutizare a simptomelor neurologice este orientat către Clinica Medicală a Spitalului "Dr. C. I. Parhon" Iaşi pentru continuarea investigaţiilor şi conduită terapeutică.

Din antecedentele patologice personale menţionăm hipertensiune arterială aterosclerotică şi cardiopatie ischemică cronică din 2008 şi un accident ischemic tranzitor în martie 2009. Antecedentele heredo-colaterale sunt nesemnificative.

La domiciliu se afla sub tratament cu Rosuvastatină 5 mg x 1 cp/zi, Clopidogrel 75 mg (1 cp/zi), Detralex 500 mg (2 cp/zi), Milgamma (2 cp/zi), Diurex 50 mg (1 cp/zi), Pentoxifilin Retard 400 mg (2 cp/zi), Betaserc 24 mg (2 cp/zi). Neagă consumul de analgezice de tipul metamizol sodic sau acetaminofen.

De menţionat expunerea pasivă la pesticide (substanţe de stropit copacii în urmă cu două luni).

Examenul clinic: febră (la internare 39ºC), tegumente uscate cu pliu cutanat persistent, limbă saburală, congestie orofaringiană cu tumefacţie şi congestie amigdaliană, tensiunea arterială TA=110/70 mmHg, frecvenţa cardiacă FC= 86 b/min.

Prezentăm cazul unui bărbat de 84 ani care este adresat Clinicii Medicale de către Spitalul de Neurologie unde se află în evidenţă pentru investigarea unei leucopenii febrile însoţite de deshidratare importantă în absenţa oricărei medicaţii medulotoxice. Menţionăm că pacientul a fost expus pasiv la pesticide (substanţe de stropit copacii) în urmă cu două luni.

Ipoteze de diagnostic clinic a sindromului febril:

1. Leucopenie febrilă de cauză leucemică (leucemie acută formă aleucemică). Argumente pro: numărul scăzut de leucocite plus febră înaltă.

2. Stare septică de etiologie neprecizată. Argumente pro: febra prelungită, înaltă asociată cu leucopenia ce poate sugera sepsis sever.

3. Deshidratare secundară febrei. Argumente pro: febră înaltă si tegumente uscate cu pliu cutanat persistent.

4. Angina eritematoasă. Argumente pro: febră, congestie orofaringiană şi congestie şi tumefacţie amigdaliană, disfagie pentru lichide şi solide.

5. Endocardită bacteriană subacută. Argumente pro: stare febrilă, pacient vârstnic; argumente contra: absenţa suflurilor cardiace şi a semnelor clinice de decompensare cardiacă dreaptă sau stângă.

Din explorările paraclinice observăm:

10.10.2010

GA = 1000 /mm³, Hb = 13,5g/dL, Ht = 39,2%, Tr = 281.000/mm³, VSH = 95mm/1h

11.10.2010

GA = 660/mm³, GR = 3.710.000/mm³, Hb = 11,6g/dL, Ht = 35,3%, VEM = 95,1/fL, HEM = 31,3/pg, CHEM = 32,9g/dL, Tr = 278.000/mm³, VSH = 103mm/1h

13.10.2010

GA = 490/mm³, Ly% = 93,9%, Ly = 460/mm³, Neutrofile% = 4,1%, Neutrofile = 20/mm³, Monocite% = 2%, Monocite = 10/mm³, Basofile = 0/mm³, Eosinofile = 0 mm³, GR = 3.210.000/mm³, Hb = 9,9g/dL, Ht = 30,3%, VEM = 94,4/fL, HEM =

30,8/pg, CHEM = 32,7g/dL, VSH = 124 mm/h. Hemoculturi negative; urocultură negativă; exudat faringian negativ.

Datorită agravării leucopeniei cu neutropenie chiar de la prima determinare şi faţă de cea de la Spitalul de Neurologie se decide efectuarea puncţiei medulare din creasta iliacă şi a frotiului din sânge periferic.

Rezultatele puncţiei medulare din creasta iliacă infirmă suspiciunea clinică de leucemie acută forma aleucemică, cu absenţa blaştilor pe toate liniile celulare şi deviere discretă la stânga a curbei de maturaţie a neutrofilelor.

Rezultatele frotiului de sânge periferic: anizocitoză cu normocromie, leucopenie severă cu limfocitoză relativă, limfocite de aspect normal.

Transaminazele crescute în dinamică (TGP = 74UI/L până la 193 UI/L; TGO = 80 UI/L până la 151 UI/L) au impus efectuarea serologiei virale hepatice care a fost negativă atât pentru hepatita virală B cât şi hepatita virală C.

Funcţia renală este în limite normale (clearance-ul de creatinină (MDRD) = 140 ml/minut/1,73m² s. c.).

Electrocardiograma (EKG) de repaus evidenţiază la internare (Fig.1): extrasistole ventriculare şi supraventriculare fără tendinţă la sistematizare, supradenivelare de segment ST de 2,5mm cu undă T bifazică din V2 până în V4; iar la externare ritm sinusal, segment ST izoelectric şi undă T bifazică din V2 până în V4.

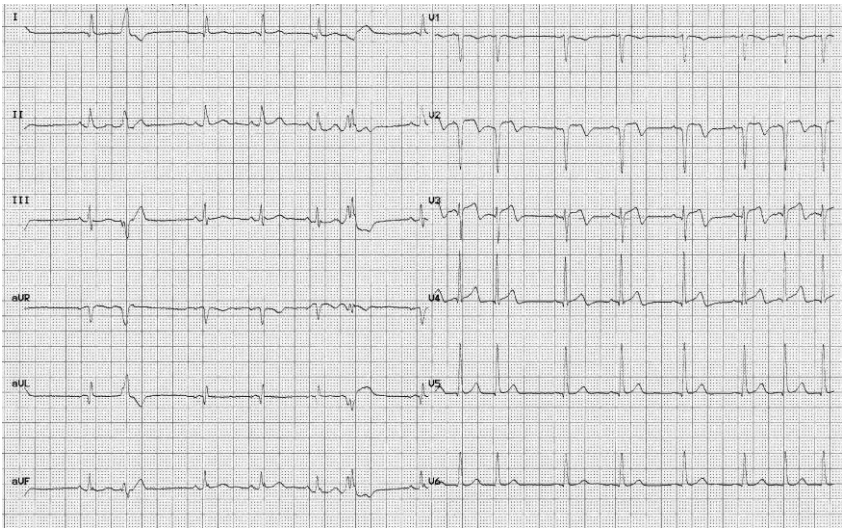

Fig. 1. EKG la internare: extrasistolie supraventriculară şi ventriculară şi modificări ischemo-lezionale în teritoriul antero-septal

Ecocardiografic: valvă aortică cu închidere şi deschidere corectă, valvă mitrală cu deschidere corectă şi închidere incompletă, cu mic prolaps. Insuficienţă mitrală gradul I, insuficienţă tricuspidiană gradul I/II prin dilatarea inelului tricuspidian. Vena cavă inferioară nedilatată (16mm), colaps inspirator complet, presiunea sistolică a arterei pulmonare 38 mmHg - hipertensiune pulmonară uşoară. Atriul stâng cu dimensiuni normale, crosa aortei, aorta abdominală şi aorta ascendentă de dimensiuni normale.

Absenţa vegetaţiilor.

Ecografia abdominală evidenţiază colecist cu multiple imagini hiperreflectogene, cea mai mare peste 11mm şi alte imagini de adiţie aderente de perete- polipi colesterolotici. Prostata global mărită, asimetrică cu întinse zone de necroză.

Consultul urologic decelează adenom periuretral.

Examenul clinic coroborat cu examenele paraclinice orientează către următoarele diagnostice:

1. Neutropenie febrilă severă de cauză toxică (expunere pasivă la pesticide).
2. Hepatită toxica post-expunere la pesticide.
3. Angină eritematoasă.
4. Angină pectorală agravată.
5. Hipertensiune arterială aterosclerotică.
6. Status post-accident ischemic tranzitor.
7. Adenom periuretral.
8. Polipi colesterolotici vezicula biliară.

DISCUŢII

Datorită vârstei înaintate şi a severităţii neutropeniei prognosticul a fost rezervat încă de la internare. Reducerea progresivă şi semnificativă a globulelor albe şi a neutrofilelor a impus introducerea imediată (după recoltarea uroculturii, hemoculturii şi a exudatului faringian) a antibioterapiei în triplă asociere şi cu spectru larg vizând şi anaerobi (Metronidazol 250mg/zi, Cefort 1gx2/zi şi Tazocin 4,5gx3flacoane/zi).

De asemenea, severitatea afectării liniei granulocitare a necesitat consult hematologic opiniându-se pentru stimulare medulară cu Metilprednisolon i.v. şi factor de stimulare a granulocitelor (Neupogen 48 MUI/0,8ml/zi timp de trei zile). Pacientul a fost izolat restricţionându-se accesul vizitatorilor.

Pentru afecţiunea cardiacă a primit tratament anticoagulant (Fraxiparină), tratament coronarodilatator (ISDN), α şi β-blocant (Carvedilol) cu evoluţie favorabilă a aspectului EKG, menţionând că pacientul a fost permanent asimptomatic.

Pentru deshidratarea secundară febrei a fost hidratat zilnic pe toată durata spitalizării.

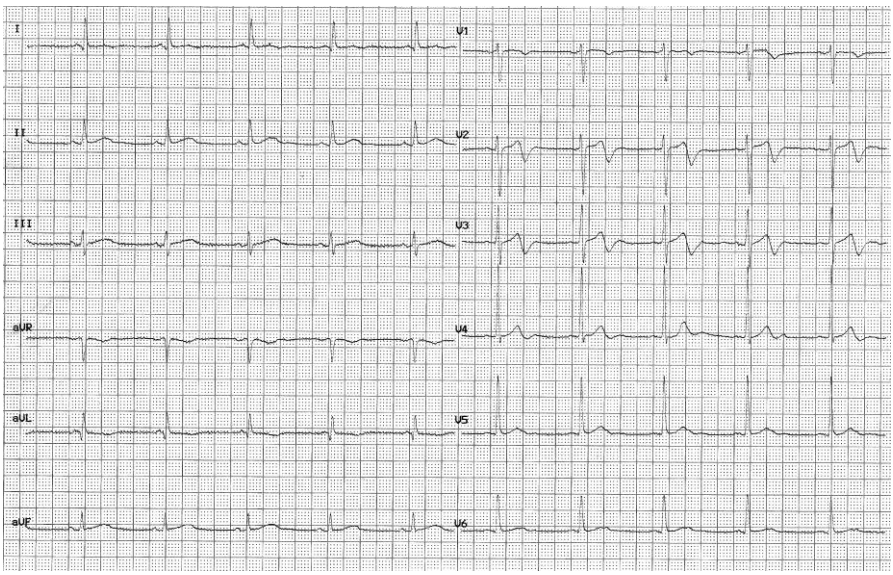

Fig. 2. EKG la externare: unde T ischemice

Evoluţia a fost lent favorabilă cu obţinerea afebrilităţii sub tratament antibiotic şi creşterea progresivă a numărului de globule albe după stimularea cu Metilprednisolon şi factor de stimulare a granulocitelor (GA= 6980/mm³, Neutrofile= 49%).

Probele hepatice s-au normalizat la controlul efectuat la externare considerând că afecţiunea hepatică a fost secundară expunerii pasive la pesticide.

Pacientul a fost externat după 17 zile de la internare fiind afebril, cu hemoleucograma, funcţia hepatică, renală şi electrocardiograma (Fig.2) în limite normale, apetit îmbunătăţit şi autonomie păstrată. La trei şi la şase luni de la externare controlul hematologic a fost în limite normale.

PARTICULARITATEA CAZULUI

Constă în vârsta înaintată, sexul masculin (ştiind că afecţiunea apare mai frecvent la adultul cu vârsta cuprinsă între 30-70 ani şi îndeosebi la femei) şi răspunsul prompt la administrarea de factor de stimulare a granulocitelor timp de trei zile, cu menţinerea normală a numărului de leucocite (pe toate liniile) la trei şi la şase luni de la administrare.

De notat reacţia particulară după expunerea pasivă la pesticide deşi nu sunt citate în literatură cazuri de medulotoxicitate secundară.

2. Clinica a IV-a Ginecologie

OVARIAN TUMORS OF LOW MALIGNANT POTENTIAL (BORDERLINE OVARIAN TUMORS) (Abstract): Ovarian borderline tumors are rare, their good prognosis depending on their stage at the time of diagnosis, and the presence of invasive implants. There is little information on tumor type identified intra-surgically, as well as on the most favorable treatment in borderline ovarian tumors. **Aim:** To determine the criteria of identification and pre-surgery and intra-surgery differentiation of the ovarian borderline tumors from the invasive carcinoma and benign ovarian tumors. **Material and methods:** This study included 54 patients with TPMS (ovarian borderline tumors) surgically treated in the past 22 years (January 1988-December 2009) at the 4th Gynecological Clinic of the Iasi "Gr. T. Popa" University of Medicine and Pharmacy. In this interval 1,107 ovarian tumors: 575 benign, 478 malignant, and 54 TPMS (4,87%) were recorded. The age of the patients with borderline tumors ranged between 20 and 78 years, mean age 46 years, and the histological types were: mucinous (27 cases), serous (18 cases), mixed (8 cases), and Brenner tumor (1 case). **Results:** We have analyzed the distribution of these cases according to the time when surgical treatment was performed. The frequency of borderline ovarian tumors in our study is 4,87%, lower than in the literature. We believe that this low percentage in our study is due to missing the microscopic data in some macroscopic benign tumors. **Conclusions:** By this research we aimed at elaborating a therapeutic strategy for each case using with discernment the modern treatment (surgery, chemotherapy, radiotherapy), as well as new chemical drugs with the goal of obtaining better results and longer survival. There are no tumor markers which could predict the progression of a borderline ovarian tumor to invasive tumors, but the invasive course is only 0,7%. **Key words:** BORDERLINE TUMOR, INVASIVE AND NON-INVASIVE TUMOR

Tumorile ovariene cu potențial malign scăzut (TPMS) sau tumorile ovariene borderline au fost descrise inițial de H.C. Taylor (1929) şi clasificate de F.I.G.O. în 1973(1). Caracteristicile acestui tip tumoral sunt: a) proliferare epitelială, formare de papile, pseudo-stratificare; b) prezența unor elemente de morfologie malignă ca atipii nucleare, activitate mitotică intensă; c) absența invaziei stromale adiacente (imagine strict caracteristică). TPMS sunt entități rare, cu un prognostic bun, dependent de stadiul tumoral în momentul diagnosticului (2). Frecvența lor variază între 9% şi 20% din toate tumorile epiteliale ovariene. Diagnosticul se pune frecvent în stadii inci-

piente, supraviețuirea mai mult de 5 ani ajungând până la 100%(3).

MATERIAL ŞI METODĂ

Sunt prezentate 54 de cazuri cu TPMS înregistrate în Clinica a-IV-a Ginecologie a U.M.F. "Gr. T. Popa" Iaşi, în perioada ianuarie 1988-decembrie 2009. Au fost analizați următorii factori: vârsta, antecedentele, stadiul tumoral, localizarea, dimensiunile tumorale, starea capsule, tipul histologic, microinvazia, tratamentul, prognosticul. În intervalul precizat, în Clinica a-IV-a au fost operate 1107 tumori ovariene astfel: 575 benigne, 478 maligne, 54 TPMS (4,87%). Vârstele limită ale tumorilor borderline au fost 20, respectiv 78 ani, iar vârsta medie 46 de ani (tab. I şi tab. II).

TABELUL I

Distribuția pacientelor din studiu după criteriul vârstei, pe intervale de vârstă şi după vârstă principală, medie, minimă şi maximă la Clinica a-IV-a Iaşi

Nr. crt.	Vârsta (ani)	Paciente (număr)	Paciente (procent)	Vârsta minimă	Vârsta medie	Vârsta maximă
1	15 - 25	7	12.9%	20		
2	25 – 35	6	11.11%			
3	35 – 45	12	22.22%			
4	45 - 55	12	22.22%		46	
5	55 – 65	11	20.37%			
6	65 – 75	4	7.4%			
7	75 - 85	2	3.78%			78
8	TOTAL	54	100%			
9	Vârsta principală	55				

TABELUL II

Prevalența cazurilor de TPMS în relație cu numărul de tumori de ovar maligne, respectiv benigne operate la Clinica a-IV-a Iaşi în perioada ianuarie 1988-decembrie 2009

Nr. crt.	Anul tratamentului chirurgical	Total cazuri TPMS	Nr. crt.	Anul tratamentului chirurgical	Total cazuri TPMS
1	1988	--	12	1999	2
2	1989	2	13	2000	2
3	1990	5	14	2001	3
4	1991	--	15	2002	--

REZULTATE

Datele obținute sunt prezentate în Tabelul III şi prelucrate grafic şi în histogramă în fig. 4 şi fig. 5 pentru TPMS în stadiul I, fig. 6, fig. 7 pentru TPMS în stadiul II/III/IV, fig. 8 şi fig. 9 pentru număr şi procent total de TPMS şi fig. 10, fig. 11, fig. 12 pentru alte tipuri de TPMS în stadiul I, stadiul II/III/IV. Tratamentul a fost exclusiv chirurgical, stadiul în momentul diagnosticului permițând această conduită. A fost practicat examenul citologic peritoneal (din fluid sau după lavaj) (5) la toate cazurile.

Am analizat distribuția numărului de cazuri de TPMS în funcție de perioada de timp în care s-a fost efectuat tratamentul chirurgical şi am prezentat rezultatele în tabelul IV. Am reprezentat apoi grafic numărul total de cazuri cu TPMS în funcție de anul corespunzător în fig. 14, în histogramă tridimensională în fig. 15 şi în distribuție procentuală în fig. 16.

Proprietățile TPMS intraoperator sunt descrise în Tabelul V şi în fig. 16, fig. 17, şi fig. 18.

Tipurile de intervenție chirurgicală practicate (6) au fost: histerectomia totală (subtotală în 5 cazuri la cererea pacientelor), anexectomia bilaterală (3 cazuri), omentectomia (16 cazuri), limfadenectomia pelvină (6 cazuri). Tratamentul standard este histerectomia totală cu anexectomie bilaterală. Chirurgia conservatoare (aplicată în 3 cazuri) s-a aplicat în scopul prezervării capacității fertile. Urmărirea evoluției postoperatorii în cazurile tratate conservator este esențială (7).

DISCUȚII

TPMS formează o entitate distinctă. Termenul „borderline” poate crea o senzație de falsă securitate, motiv pentru care se impune precizarea că aceste cazuri trebuie privite drept cazuri cu cancer ovarian. Stadializarea trebuie făcută cu ocazia laparotomiei inițiale (8). Acest principiu este greu de respectat pentru că tumorile se descoperă în majoritatea cazurilor în stadiul I. Tumorile au aspect de benignitate, apartenența la categoria TPMS fiind stabilită ulterior microscopic. Preoperator, diagnosticul clinic este la fel de improbabil (9). Sonografia este utilă, iar rolul markerilor tumorali nu este precizat (10). Evaluarea chirurgicală este necesară pentru a exclude prezența leziunilor extrapelvine şi pentru realizarea diferențierii între implantele invazive şi a celor non-invazive (11). În observația noastră doar 6% din cazuri au prezentat implante invazive. Aceste implante pot influența ratele de supraviețuire şi pot indica un tratament chimic. Citologia peritoneală nu are o mare fiabilitate în estimarea prezenței implantelor (12). Semnificația implantelor peritoneale ramâne neclară, iar răspunsul la terapia adjuvantă pare a fi minim sau absent, prognosticul nefiind în mod evident influențat. Tumorile seroase sunt cele mai comune, dar în statistica noastră cel mai frecvent a fost tipul mucinos. Putem afirma că titrurile CA125 mijlocii sau ridicate au fost mai frecvente la tumorile seroase şi la cele diagnosticate în stadii mai avansate. Considerăm că diferențierea preoperatorie bazată pe nivelele CA125 este dificilă. Frecvența TPMS de 4,87% observată în studiul nostru este mai mică decât procentajele afi şate în literatură. Presupunem că această incidență redusă poate fi explicată de lipsa catalogării microscopice a cazurilor considerate macroscopic benigne. Vârsta medie a cazurilor (46 ani) este mai ridicată decât cea de 40 de ani citată în alte studii (13). Această constatare este corelată atitudinii terapeutice (14)(după vârsta de 40 de ani am recomandat histerectomia totală cu anexectomie bilaterală) (15). Tratamentul conservator a fost recomandat cazurilor ce au dorit să- şi păstreze capacitatea fertilă, în cuno ştință de cauză şi cu obligativitatea controlului post-operator. Într-un studiu publicat în Germania (G. Schumacher et al. 2009)se arată că în țările din vestul Europei se diagnostichează anual cca 4000 cazuri de TPMS. Frecvența cea mai mare ar fi la grupa de vârstă 15-29 ani (16) (diferit de ceea ce am constatat noi). Prognosticul TPMS este favorabil. Principalii factori de prognostic sunt: stadiul chirurgical, uni sau bilateralitatea, tipul histologic. Nu există markeri cu valoare predictivă pentru TPMS care evoluează spre invaziv. O analiză a 22 de serii de cazuri (total 953) a ajuns la concluzia unei rate de supraviețuire de 92%. În stadiile inițiale, transformarea invazivă se observă rar (0,7%).

CONCLUZII

Criteriile microscopice necesare încadrării tumorilor ovariene în categoria de TPMS sunt: a) hiperplazia epitelială (stratificare, aspect cribriform, micropapilar); b) atipie u şoară sau moderată; c) activitate mitotică minimă; d) absența invaziei stromale. Existența focarelor de carcinom intraepitelial nu modifică prognosticul, dar este importantă pentru tratament.Tipul micropapilar influențează negativ prognosticul. Procentajele supraviețuirilor postterapeutice la 5 ani sunt în stadiul I până la 100%. Prognosticul nu diferă semnificativ în raport cu terapia utilizată (chirurgie – metodă unică, chirurgie şi tratament adjuvant). Supravegherea post-terapeutică îndelungată este obligatorie.

CANCER GENETIC COUNSELING. PART I-WESTERN EUROPEAN COUNTRIES (Abstract): Genetic counseling services represent a relatively new concept aimed to identify patients or relatives with hereditary predisposition for cancer susceptibility and to act accordingly for early diagnosis, cure and prevention. It has become an accepted part of oncology care in many European countries. Unfortunately, despite the same state of knowledge, the patients from different European countries would experience different care. This situation is not in accordance with the European Union directives, which are enacted to implement and protect the idea of free movement of goods, services, people and capital. This study aimed to examining the current practice of genetic counseling for cancer in different European countries, with special accent on familial breast and ovarian cancer management as the most studied and managed hereditary cancer. We also sought to ascertain the needs for the unitary politics in cancer genetics services, to decrease the difference in cancer genetic counseling opportunity and facility. As a first step we compared the national guidelines regarding genetic counseling for familial/hereditary breast and ovarian cancer in some countries from Western Europe. All guidelines recommend embedding genetic testing within a framework of genetic counseling, and all agree to perform genetic testing first in an affected person. However, we found some differences regarding the thresholds, detailed description of selection criteria, the risk calculation methods, the age of diagnosis, the relationship with counselor and physician etc. There are also many open questions that are not covered by the guidelines, for instance: how to deal with phenocopies, unclassified variants, and newly identified breast cancer susceptibility genes or with family that not fitting the criteria, that need to be discussed. New evidence is usually slowly integrated into the guidelines. An exchange process towards the harmonization of the guidelines will ensure high quality health care across Europe. **Keywords:** HEREDITARY BREAST AND OVARIAN CANCER; BRCA, GENETIC COUNSELING.

Cancer genetic counseling represents one of the most innovative new concepts in healthcare. Worldwide, the number of cancer cases is 18.1 million of which 2.1 million new cases of breast cancer, 1.8 million colorectal cancers and 295,414 ovarian cancers. Worldwide, cancer is the second leading cause of death with 9.5 million deaths reported for the year 2018 by *International Agency for Research on Cancer* (IARC). Epidemiological data shows that in Europe, 4.2 million new cases of cancer were reported with 1.9 million new cases in women and 2.3 million new cases in men, according to IARC. Of the total cases recorded in Europe, ovarian cancer encoun-

tered for 67,771 new cases, being responsible for 44,576 deaths. Breast cancer is registered with a total of 522,513 new cases, with a number of 137,707 deaths (1).

Each day, worldwide, millions of people fight a battle against cancer, undergoing devastating therapies that hugely impact on their *Quality of Life*. Over the next two decades, the number of new cases is expected to rise by about 70%. Oncogenetics can contribute to change this future scenario, addressing those people for which prevention is still possible and the disease's onset avoidable. This medical discipline, in progressive expansion, is focused on understanding and monitoring the genetic predispositions of persons at risk, due to mutations or family histories of cancer. The implementation of evidence-based prevention strategies will lead to considerable improvements in clinical decisions and outcomes. In order to move towards this predictive system, it is essential to raise awareness of those vulnerable people and to empower them. On this basis, it will be possible to facilitate an appropriate checking and an early detection of prodromes, as well as the modification of harmful habits and behaviors (2).

The objective of oncogenetics is to understand genetic predisposition to cancers and care for persons at risk. Genetic predispositions are often associated with a family history of cancer. However, cancers are very frequent and family histories exist, so a family history of cancer is not synonymous with a genetic predisposition. The purpose of a genetic consultation is to determine the share of family history and possible predisposition. Genetic tests, stills seldom practiced, sometimes confirm a hereditary origin. If an alteration is identified in a family, it can be sought in its relations. This makes it possible to reassure those having no predisposition and following up those at risk (3).

However, the realization of the full potential of oncogenetic counseling requires close collaboration between diverse kind of specialists and institutions. These include researchers, clinicians, research institutions, healthcare providers, research and technological development funding agencies, public health agencies, policy makers, industry, regulatory authorities, health insurers and, crucially, the citizen. Genetic testing is already finding its way into several specific clinical applications. Breast cancer, for example, is one of disease in which enormous progress has been made in this regard (3, 4).

However, as things presently stand, the full potential of cancer genetic cancelling cannot be realized in all European countries for several reasons. These include fragmentation of European efforts, nationally and regionally restricted activities, and a lack of concerted approaches in the different areas of ontogenetical services. In addition, In Europe, despite efforts in harmonizing standards for genetic testing and further patients care management problems arise mostly due to differences in countries' health care systems and service delivery settings. Therefore, to advance ontogenetical services, it is likely to achieve strategic interaction between key European players. These include decision-makers in diverse scientific disciplines, research policy and funding, patient interest groups, different national healthcare systems, regulatory and governmental bodies and private enterprise. Only then can a well-balanced and successful development of cancer genetic services be achieved (2).

This review aimed to examining the current practice of cancer genetic counseling in different European countries with special accent on familial breast and ovarian cancer management as the most studied

and managed hereditary cancer disease. We also sought to ascertain the needs for the unitary politics in cancer genetics services.

Cancer care and genetic counseling development in Western Europe

Cancer care has always been part of the health care provided within national health systems across the EU, but only in the last 20 to 25 years, more systematic approaches formulating and applying the comprehensive national policies or plans specifically directed at improving the organization of services for people with cancer have been adopted in some countries. The rationale is that outcomes can be greatly improved by more effective clinical organization and better operational delivery of cancer services (3).

The first explicit attempt to prepare a comprehensive national cancer policy was published by the Chief Medical Officers of England and Wales in 1995 (2). The Calman-Hine report, named "Responding to the challenge of cancer in Europe after the Chief Medical Officers involved" was accepted by government as the basis for the future provision of cancer services in the United Kingdom. The first comprehensive national cancer plans followed a few years later in Denmark (National Board of Health, 2000), England (Department of Health, 2000) and France (French National Cancer Institute, 2003). All began around 2000 (3).

The next logical step was to create Cancer Centers because it could offer more expertise to treat different types of cancer at high standards and would provide sustainability to use expensive equipment for treatment and research. In this respect it can be mentioned National Institute for Health and Clinical Excellence (NICE), in UK, French National Cancer Institute (Institute National du Cancer (INCa) in France, German Consortium for Hereditary Breast and Ovarian Cancer (GC-HBOC include 12 cancer centers in Germany) - there are a few examples of the oldest Cancer Institutions in Western Europe that provide both research and clinical services (3).

Since 2000, in the most of western European countries testing for hereditary cancer susceptibility has become an integral part of medical management. At-risk individuals can be provided with regular surveillance to identify cancer at an early stage. Prophylactic surgery aims to prevent the development of cancer, and moving in the direction of personalized medicine, targeted therapies for affected mutation carriers become available. The essential step towards a rational approach is how to identify individuals who will benefit from testing, without straining the financial budget of the national health system, although recently established techniques like next generation sequencing may significantly reduce the costs (4).

Meanwhile, guidelines have been established on how to identify individuals at risk for familial breast cancer. In UK the National Institute for Health and Clinical Excellence (NICE), develop guidelines for different issues. The NICE clinical guideline (CG) 41 was created in 2004 and focuses on "Familial breast cancer: the classification and care of women at risk of familial breast cancer in primary, secondary and tertiary care". In France, access to cancer genetic services and testing is covered by the National Health Care System and since 2003 through the initiative of the Cancer Plan. "The Cancer Plan 2009-2013" has been developed by the French Ministry of Health in coordination with the French National Cancer Institute (Institut National du Cancer (INCa)). It incorporates the knowledge on hereditary predisposition to cancer within the rubric "Oncogénétique"

http://www.e-cancer.fr/soins/prises-en-charge-specifiques/oncogenetique/ (5, 6).

In the Netherlands "Erfelijke Tumoren: Richtlijnen voor Diagnostiek en Preventie" 2010 was published by the Netherlands Foundation for the Detection of Hereditary Tumors (STOET) and the Dutch Society of Clinical Geneticists (VKGN) (2). In Germany, the German Consortium for Hereditary Breast and Ovarian Cancer (GC-HBOC) was established in 1996 as a cooperative research project supported by the German Cancer Aid (Deutsche Krebshilfe). Twelve university-based interdisciplinary centers developed a standardized approach for the management of families with hereditary breast and ovarian cancer. This concept, including the genetic counselling, the molecular genetic diagnostics and the clinical surveillance, became part of the regular health care system in 2005 (3, 6).

In all these countries *genetic diagnostics* is available to search for mutations in the breast cancer genes *BRCA1* and *BRCA2* (3, 4, 5). Although a similar frequency of mutation is assumed each country has established its own genetic testing including criteria. The individual guidelines and recommendations are roughly similar for most selection criteria. All guidelines recommend embedding genetic testing within a framework of genetic counseling, and all agree to perform genetic testing first in an affected person. The access to genetic counseling differs within the countries. While in the UK and the Netherlands for referral from primary care, a general practitioner or secondary care, a specialist is required, in France and Germany referral is usual, but not obligatory. An individual also has direct access to genetic counselling. In this case, difficulties can arise for reimbursement (3).

According to French guidelines, in order to increase the percentage of detected *BRCA1/2* mutation carriers, the including criteria for genetic counselling have been extended and include isolated ovarian cancers diagnosed before the age of 70 and even at an older age (7, 8).

Regarding the approach towards genetic testing, it is recommended first to test the index patient. After a mutation is identified in index patient in all Western European countries, a predictive testing can be offered to healthy relatives from the beginning of a young adult age. The health insurance covers all genetic counseling and testing costs while the threshold for testing a family is quite different between the countries (6, 7).

Risk prediction models are known and used in each country; however, the purpose or reason for their use differs. For example, Tyrer-Cuzick or BOADICEA can be used as prediction tool in UK (9) but should not totally replace careful manual assessment of family trees by a genetic specialist. The Manchester scoring system was developed in 2003 and updated in 2009 to facilitate a simpler and more accurate selection of families for *BRCA1/2* testing (10). Although it is known that all available risk calculation models show considerable weaknesses (11, 12), Cyrillic 2.1 is a helpful tool and allows uniform decision-making across Germany. Thresholds of a risk of heterozygosity of ≥20% or a residual lifetime risk for breast cancer of ≥30% qualify a woman for management in the high-risk group (3).

Recommendations for the clinical management have also been developed. Intensified surveillance strategies including MRI screening and prophylactic surgical options are offered for people who caring a mutation in all western European countries.

There are some specific accents in different county guidelines. In the current French guidelines, the prenatal or preim-

plantation diagnostics could be allowed for people with cancer syndromes after a favorable assessment by a specific advisory board. The request for opinions of French cancer geneticists and prenatal center professionals can differ according to the type of hereditary cancer involved (2, 4).

Furthermore, the Dutch guidelines for clinical geneticists take into consideration the occurrence of phenocopies among breast tumors and deal with unclassified variants (UV) as genetic test results. It is suggested to perform segregation analysis within the family to clarify the effect of the UV (13).

In the German Act on Genetic Diagnostics (14) informed consent is defined as the main purpose of the law, which regulates the conditions for genetic analysis and utilization of genetic data to avoid disadvantages and discrimination. The right "not-to-know" is deeply anchored in the law and has the same value as the right "to-know". Before a genetic test can be initiated, the test person must be informed about the prospects and limitations of the test at-issue as well as about the consequences of the possible results and must agree to the test in written form. In the case of predictive genetic testing, pre- and post-test genetic counseling is mandatory, and refusal must be documented (3, 15).

CONCLUSIONS

Despite a real progress on genetic testing a further data management at the European level, there was a lack of consensus about the best way to carry out genetic counselling, which meant that there were many different approaches to this subject. Counseling has been an area that has had a widespread investigation, leading to each country coming up with its own legislations, guidelines and definitions. Due to this, at a European level, the EuroGenTest (www.eurogentest.org) was established to "*harmonize genetic testing across Europe.*" This was a tool developed to aid professionals of genetic counseling and allowing the creation of a network that would help in the sharing of experiences and information between health professionals also aids patients to understand their rights and to guide them through genetic testing and genetic counseling. A reasonable approach to harmonize the thresholds for inclusion criteria and other guidelines details would be beneficial. It could be a compromise between the strict family history-orientated NICE guidelines from the UK and the less constrained French criteria. The Dutch and German guidelines already represent something in between, so it could be a good start for guidelines harmonization. Only the Dutch guidelines take into consideration the phenomenon of phenocopies, and triple-negative tumors within *BRCA1*-associated breast cancer. There are still a lot of open questions as families with male relative or the situation that no index patient is available for testing that are not covered in any guidelines. A simple scoring method to classify the family, like the Manchester scoring system, seems to be a reasonable and an easy to use tool and suitable to assert throughout different European countries. Guidelines must be orientated on different levels and disciplines, and the access for every player involved should be thereby facilitated. General practitioners, clinical specialists, geneticists and researchers need different information and different support for decisions. An open communication process including all these topics seems most promising to react adequately to the current level of knowledge and to improve the quality of genetic counselling and testing for familial/ hereditary breast and ovarian cancer across Europe.

PERIPHERAL VESTIBULAR SYNDROME INTRICATED PATHOGENIC ISSUES. A CASE REPORT (Abstract): **Background**: Ménière's syndrome appears to be the final common pathway of the mechanisms the inner ear responds to almost any injury. Although the autoimmune disease seems to play a major role, exposure to intense noise can also be a trigger in the appearance and/or aggravation of the disease. **Material and methods**: The case of 41 years old musician with a history of ankylosing spondylitis, diagnosed with Ménière's syndrome 5 years ago, is presented. Recently the symptoms became more polymorphic, revealing the association between benign paroxysmal positional vertigo (BPPV), Ménière's syndrome and high frequency hearing loss in an autoimmune background. Besides general, neurological and ENT examination, the diagnostic workup comprised of tonal audiogram, brain stem auditory evoked potentials, computerized dynamic posturography and videonistagmography. **Results**: The final diagnosis was acute noise trauma, Ménière's syndrome, left horizontal semicircular canal BPPV, bilateral sensorineural sudden aggravated hearing loss in high frequencies (above 9 kHz) and allegedly autoimmune inner ear disease. Treatment with an association of corticosteroids, vasodilators and vitamins combined with Vannucchi's maneuver were followed by a significant relief of the symptoms. **Conclusion**: Although no causal relationship was found between acoustic trauma and increased endolymphatic pressure, both literature data and the case presented show that intense and prolonged noise exposure may aggravate peripheral vestibular syndrome. **Keywords**: MÉNIÈRE´S DISEASE, BENIGN PAROXYSMAL POSITIONAL VERTIGO, AUTO-IMMUNE DISEASE

Prosper Ménière a dat numele său unei afecţiuni a urechii interne ce se manifestă prin episoade recurente de vertij rotator, hipoacuzie fluctuantă şi acufene. Această afecţiune poate fi: idiopatică (boala Ménière) sau secundară unor variate afecţiuni ale urechii interne care au ca rezultat tulburarea mecanismului de producere sau resorbţie a endolimfei (sindrom Ménière).

Majoritatea autorilor consideră că boala Ménière se asociază în mod obligatoriu hidropsului endolimfatic (1). Studii recente au arătat că această asociere patogenică nu este obligatorie: unii pacienţi cu boala Ménière nu au hidrops endolimfatic, iar hidropsul endolimfatic fără asocierea simptomelor caracteristice bolii Ménière este mult mai frecvent identificat (6%), comparativ cu prevalenţa bolii Ménière de numai 0,2% (2).

Sindromul Ménière pare a fi modalitatea comună prin care urechea internă răspunde la aproape orice agresiune (sistemică sau locală). Există o relaţie de cauzalitate între afecţiunile autoimune şi sindromul Mé-

nière, cercetări recente evidenţiind rolul imunologic al sacului endolimfatic al urechii interne (3). Terenul autoimun poate cauza sau se poate asocia cu boala autoimună a urechii interne (hipoacuzie bilaterală lent progresivă, uneori fluctuantă, acufene, crize vertiginoase). Deşi incidenţa bolii autoimune a urechii interne este redusă, sub 1% din toate cazurile cu hipoacuzie şi vertij, la 16 % dintre pacienţii diagnosticaţi cu boală Ménière această afecţiune este secundară disfuncţiei autoimune (4).

Spondilita anchilopoetică face parte din categoria bolilor reumatice autoimune. În 28% din cazuri s-a observat asocierea acesteia cu apariţia hipoacuziei neurosenzoriale bilaterale (3).

Pe de altă parte, expunerea la sunete/ zgomote intense poate constitui un trigger în apariţia simptomelor caracteristice bolii Ménière. Astfel, în plan fiziopatologic, creşterea presiunii endolimfei, poate fi implicată în apariţia vertijului paroxistic poziţional benign (VPPB) prin dislocarea fragmentelor otoconiale şi deplasarea lor la nivelul unuia sau a mai multor canale semicirculare. Există pacienţi la care, în evoluţie, se pot asocia mai mulţi factori etiologici, în aceste cazuri diagnosticul fiind mai dificil.

PREZENTAREA CAZULUI

Prezentăm cazul unui pacient în vârstă de 41 ani, muzician. Acesta a prezentat, începând din anul 2005, crize de vertij rotator însoţit de greţuri şi vărsături, instabilitate ortostatică cu tendinţă de deplasare spre partea stângă. Crizele au avut următoarele caracteristici : debut brusc, durata 24-48 de ore, remisiunea manifestărilor acute fiind urmată de persistenţa unei senzaţii de ameţeală, epuizare fizică şi psihică. Consultul neurologic şi rezonanţa magnetică nucleară cerebrală, efectuate după prima criză, nu identifică existenţa unor elemente patologice. Simptomatologia s-a reprodus cu o frecvenţă de 1-2 crize/an până în septembrie 2009 când devine polimorfă prin apariţia în cadrul tabloului clinic a hipoacuziei şi acufenelor la nivelul urechii stângi, precum şi a senzaţiei de plenitudine aurală stângă. Pacientul s-a adresat serviciului nostru, unde a beneficiat de investigaţiile clinice şi paraclinice disponibile în momentul respectiv din care rezulta prezenţa unei funcţii auditive şi vestibulare normale. Şi de această dată explorările imagistice cerebrale (computer tomografie şi rezonanţă magnetică) nu au identificat elemente patologice. Din luna mai 2010 crizele pacientului au devenit mai frecvente, motiv pentru care revine în clinică. Dispozitivele achiziţionate recent permit efectuarea audiogramei pe frecvenţele înalte (care identifică o pierdere de auz bilaterală pe frecvenţele mai mari de 9000 Hz, simetrică, de 40-50dB) precum şi evaluarea funcţiei vestibulare cu ajutorul posturografiei dinamice computerizate (explorarea fiind efectuată înafara crizei nu obiectivează prezenţa unui deficit vestibular). După ultima criză, în august 2010, pacientul relatează, alături de simptomatologia descrisă mai sus, accentuarea bruscă a hipoacuziei şi a acufenelor la nivelul urechii stângi împreună cu evitarea decubitului lateral pe partea stângă, această poziţie agravând senzaţia vertiginoasă şi simptomatologia vegetativă.

Condiţiile de viaţă şi muncă prezintă o mare importanţă la acest pacient. Trebuie remarcat faptul că pacientul este muzician activând într-o orchestră, lucru important deoarece în mare parte crizele de vertij au debutat în timpul concertelor sau al repetiţiilor.

Dintre antecedentele personale patologice reţinem diagnosticul de spondilită anchilopoetică (în anul 2000) pentru care a urmat tratament cu salazopirină (timp de 6 luni) şi ulterior cu antiinflamatorii nesteroidiene.

Examenul clinic pe aparate şi sisteme împreună cu cel ORL au fost în limite normale. Evaluarea pacientului a inclus bilanţul

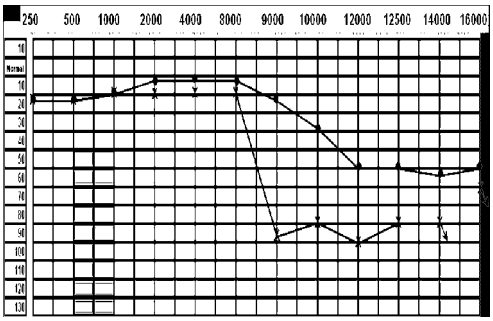

Fig. 1. Audiogramă extinsă – august 2010 (hipoacuzie brusc agravată pe urechea stângă)

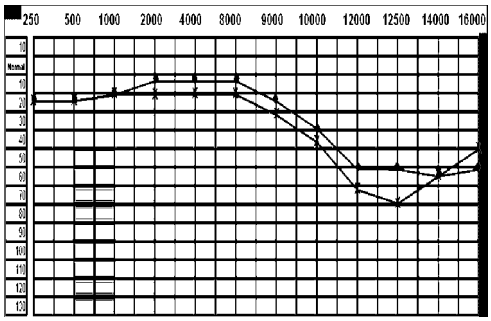

Fig. 2. Audiograma extinsă – mai 2010 (hipoacuzie simetrică bilaterală)

audiologic şi al funcţiei vestibulare. Astfel, la evaluarea audiologică s-au obţinut următoarele rezultate : timpanogramă tip A bilateral, audiogramă tonală liminară extinsă accentuarea deficitului auditiv la nivelul urechii stângi (fig.1) comparativ cu pragurile auditive identificate la prima audiogramă de acest tip efectuată în mai 2010 când pierderea auditivă avea un aspect simetric bilateral (fig.2).

S-au efectuat potenţiale evocate auditive de trunchi cerebral cu parametri în limite normale, fără a identifica elemente de suferinţă retrocohleară.

Evaluarea funcţiei vestibulare s-a realizat şi de această dată, înafara crizei. Nu s-a constatat prezenţa unui deficit vestibular în cadrul examenului clinic sau prin posturografia dinamică computerizată (PDC).

Videonistagmografia (VNG) aduce elemente noi prin studiul nistagmusului şi prin proba calorică. Se observă prezenţa nistagmusului poziţional declanşat de manevra de provocare McClure (rotirea capului aflat în poziţie orizontală spre părţile laterale). După efectuarea manevrei pentru partea stângă, se înregistrează, cu o scurtă perioadă de latenţă, nistagmus orizontal ageotrop ce se epuizează în 30 secunde (pe plan subiectiv pacientul relatează apariţia vertijului şi a senzaţiei de greaţă). Se formulează astfel diagnosticul de VPPB de canal semicircular orizontal (CSO) stâng. Prin proba calorică se identifică hipovalenţa vestibulului stâng.

Astfel, în urma analizării datelor anamnestice şi a rezultatelor investigaţiilor prezentate se formulează diagnosticul pozitiv de : traumă sonoră acută, sindrom Ménière, VPPB de canal semicircular orizontal stâng, hipoacuzie neurosenzorială bilaterală pe frecvenţe înalte (peste 9 kHz) şi observaţie de boală autoimună a urechii interne.

În acest context s-a considerat util tratamentul corticosteroid sub protecţie gastrică, vasodilatator şi vitaminic, alături de manevra de repoziţionare prelungită descrisă de Vannucchi (decubit lateral pe partea sănătoasă timp de 12 ore).

Evoluţia la finalul tratamentului a fost favorabilă : audiograma de control arată ameliorarea uşoară a hipoacuziei (10 dB), reducerea intensităţii acufenelor la nivelul urechii stângi, dispariţia nistagmusului poziţional la videonistagmografie.

DISCUŢII

La cazul descris mai sus putem scoate în evidenţă patru particularităţi care pretează la discuţii :

- formularea diagnosticului de sindrom Ménière şi a posibilei etiologii a acestuia
- rolul pe care mediul profesional îl are în declanşarea crizelor din sindromul Ménière
- dacă morfologia curbei audiometrice (cu afectarea frecvenţelor înalte, iniţial

simetrică şi bilaterală) se datorează terenului autoimun prezentat de pacient sau unei traume sonore cronice la care a fost expus prin natura profesiei sale

- intricarea patogenică în cadrul tabloului clinic de sindrom vestibular periferic între VPPB, sindromul Ménière şi boala autoimună a urechii interne

Este bine documentată în literatura de specialitate dificultatea stabilirii diagnosticului de boala/sindrom Ménière deoarece majoritatea pacienţilor nu prezintă la debut întreaga triadă simptomatică caracteristică acestei afecţiuni.

Putem include în această categorie şi cazul clinic prezentat : pacient cu crize de vertij de tip periferic dar fără acuzele cohleare caracteristice bolii Ménière (hipoacuzie neurosenzorială fluctuantă sau stabilă cu afectarea frecvenţelor grave). La acest pacient diagnosticul de sindrom Ménière a fost formulat respectând criteriile Academiei Americane de Otorinolaringologie pentru diagnosticul acestei afecţiuni (4). Conform acesteia, există o categorie aparte de pacienţi care prezintă numai simptome vestibulare (vertij asemănător celui din Ménière) fără asocierea hipoacuziei neurosenzoriale caracteristice. La aceştia se poate formula diagnosticul de posibilă boală Ménière monitorizarea evoluţiei urmând să constate întregirea tabloului clinic într-o perioadă variabilă de timp. Într-un studiu retrospectiv Jeffrey şi colaboratorii au observat că în grupul cu posibil Ménière vestibular existenţa hipoacuziei nu este exclusă, însă aceasta este atipică (5).

Obiectivarea prin teste specifice a bolii autoimune a urechii interne (dozări de anticorpi anticohleari, antiendoteliali, antisulfoglucuronozil) nu este posibilă datorită faptului că nu dispunem de metode fiabile cu un grad înalt de reproductibilitate care să fie utilizate pe scară largă. Suspiciunea de boală autoimună a urechii interne a fost ridicată pe baza anamnezei (pacient diagnosticat cu o afecţiune autoimună), aspectului audiogramei (obiectivarea unei hipoacuzii bilaterale cu afectarea frecvenţelor înalte, simetrice, lent progresive) şi a probei terapeutice.

Stabilirea unei relaţii de cauzalitate între expunerea ocupaţională la zgomot şi dezvoltarea unei disfuncţii vestibulare (vertij/sindrom Ménière) constituie o preocupare activă. Deşi studiile experimentale pe animale au arătat că în 35% cazuri trauma sonoră sau expunerea cronică la sunete de mare intensitate produce modificări histologice la nivelul labirintului vestibular asemănătoare hidropsului endolimfatic la om acesta relaţie nu a fost demonstrată (6). Totuşi prin expunerea pacienţilor diagnosticaţi cu boală Ménière la sunete grave de înaltă intensitate s-a observat o sensibilitate ridicată a acestora la aceasta categorie de sunete consecinţa expunerii fiind declanşarea simptomatologiei vestibulare posibil prin efect Tullio (energia sonoră activează receptorii vestibulari) (7). În cazul clinic prezentat expunerea profesională la zgomot este posibil să fi contribuit la creşterea frecvenţei de apariţie a crizelor bolii Ménière, fapt susţinut de anamneză şi de evoluţia favorabilă sub protecţie fonică.

Intricarea simptomelor vertijului paroxistic poziţional benign în tabloul clinic al acestui pacient este susţinută de datele din literatura de specialitate. Se arată că boala Ménière poate predispune pacienţii la apariţia episoadelor de VPPB. Repercusiunile histopatologice ale hiperpresiunii endolimfei asupra maculei utriculare şi saculare reprezintă, probabil, mecanismul care explică coexistenţa bolii Ménière şi a VPPB (8).

În general, la pacienţii cu sindrom Ménière unilateral, vertijul paroxistic poziţional benign a apărut pe aceeaşi parte. Doar rareori VPPB a afectat ambele părţi în cazul pacienţilor cu boala Ménière unilaterală (8). Explicaţia se regăseşte probabil în modificările histopatologice ce apar şi la nivelul urechii interne aparent indemne în

cazul pacienţilor cu boala Ménière unilaterală, modificări identificate prin studii histopatologice realizate pe oase temporale umane ale unor pacienţi diagnosticaţi cu această afecţiune (9).

CONCLUZII

Există pacienţi la care, în evoluţie, se pot asocia mai mulţi factori etiologici ai sindromului vestibular periferic, în aceste cazuri diagnosticul fiind mai dificil.

Cazul prezentat este particular atât datorită asocierii unor afecţiuni între care poate exista relaţie de cauzalitate (spondilita anchilopoetică, hipoacuzie bilaterală, sindrom Ménière, vertij paroxistic poziţional benign), cât şi prin activitatea sa (muzician) prin care se expune la o agresiune suplimentară asupra urechii interne, accentuând asocierea patogenică prezentată.

HISTOLOGIC AND IMMUNOHISTOCHEMICAL ASSESSMENT OF GINGIVAL TISSUE'S CHANGES INDUCED BY PERIODONTAL DISEASE IN ASSOCIATION WITH CHRONIC HEPATITIS C (Abstract): Periodontal disease and chronic hepatitis C are two types of chronic inflammatory reactions that target the supporting tissues of the teeth and the liver tissue, respectively. Common pathogenic pathways may be shared by the two types of disease, which the current study **aims** to histologically assess within the gingival tissue. **Material and methods:** The study comprised of gingival tissue samples, originating from periodontal patients with asymptomatic chronic hepatitis C and from periodontal patients with no systemic illness (collected during periodontal surgery), as well as from healthy control subjects (collected during extraction of maxillary premolars for orthodontic reasons). Upon standard histological preparation, part the samples were stained with hematoxylin-eosin technique and part were subjected to immunohistochemistry reaction for matrix-metalloproteinase-9 (MMP9) detection. **Results** revealed inflammatory morphopathological changes, which were significantly more intense and more frequent within the tissue samples of periodontal patients with chronic hepatitis C, than in those of systemically healthy ones with periodontal disease. The coloring reaction, used to evaluate the existence of MMP9 within the tissue samples, was significantly more positive for the group of periodontal and chronic hepatitis C patients than for the group of periodontal patients with no systemic illness. **Conclusions:** the inflammatory reaction is more intensive in the gingival tissue of periodontal patients with chronic hepatitis C than in that of periodontal patients without systemic conditions, proving the additional negative impact that the viral hepatic disease has on the inflammatory status, which periodontal disease involves.
Keywords: HISTOLOGY, GINGIVAL TISSUE, MATRIX-METALLOPROTEINASE 9, PERIODONTAL DISEASE, CHRONIC HEPATITS C.

Periodontal disease consists of a chain of pathological events triggered by the interactions occurring between the bacterial plaque and the host immune response, which are mediated by certain local and systemic additional risk factors (1, 2). Usually, the inflammatory reaction is firstly manifested within the marginal periodontium, the gingiva, afterwards gradually progressing towards the deeper structures which support the teeth, as the periodontal ligament and alveolar bone (3).

From a histopathological standpoint, the inflammatory events which occur during periodontal disease have been divided into four types of morphopathological lesions, named after their moment of manifestation: the initial, the early, the established and the advanced lesions (4). Each of these types of lesions present their own morphopathological characteristics, generated by the events that unveil during periodontal inflammation at a specific moment. From a clinical standpoint, these stages of inflammation cannot be always divided and observed, as they unveil with speed and at the same time in different areas of the periodontium (5).

The severity and extent of periodontal inflammation is closely influenced by the efficiency of the immune cells' chemotactism and phagocytosis that enable them to pursue and attack bacteria (6). Some periodontal pathogens such as *Porphyromonas gingivalis* and *Fusobacterium nucleatum* can inhibit cellular phagocytosis and have a cytotoxic effect on the immune cells (7). Therefore, periodontal disease's pathogeny is not fixable by the usual defensive mechanisms of the human organism and will develop into a chronic, prolonged inflammatory reaction that causes the destruction of the supporting tissues of the teeth.

Collagen is an important component of the periodontium and has a major role in keeping the right structure and function of the periodontal tissues (8). During periodontal inflammation, collagen fibers are damaged by the decreased pH and the collagenolytic enzymes secreted by bacteria. In addition, the production of new collagen is also perturbed, and immune cells can cause the dissolution of collagen by releasing matrix-metalloproteinase (MMPs) enzymes (9, 10, 11). As a result, the periodontal tissues lose their flexibility and are gradually destroyed, causing the teeth to become mobile.

MMP9, also called gelatinase-B, is an important member of the MMP enzyme family and it is found in increased levels in inflamed gingival tissues (12, 13). The main action of MMP9 is to disintegrate collagen fibers contained by gingival tissue, periodontal ligament and alveolar bone, as early as the first week of periodontal inflammation (14). Secreted by immune cells such as fibroblasts and macrophages, MMP9 can alter the chemotactic patterns of neutrophil and keratinocyte cells and can disrupt the healing process occurring inside the gingival epithelium, thus extending the inflammatory reaction (15, 16). The enzyme also stimulates the activation of some pro-inflammatory markers like interleukin 1β, further enhancing the development of periodontal inflammation (17, 18).

Chronic hepatitis C is the prolonged inflammation of the liver caused by the infection with hepatitis C virus (19). Metabolic and immune changes occur during the condition, as the liver plays an important role in the modulating of these systems (20). These changes also manifest orally, making hepatitis C patients more prone to other inflammatory disease such as periodontal

disease (21).

The aim of our study was to histologically assess the changes that occur within gingival tissues during periodontal inflammation in patients with chronic hepatitis C and to evaluate if the intensity of the inflammatory reaction is higher in such patients than in periodontal patients without systemic conditions

MATERIAL AND METHODS

The study included patients who addressed the Periodontology Department of the University of Medicine and Pharmacy of Craiova, for various periodontal complaints and was approved by the university's ethics committee. Upon signing the informed consent of participation, the patients were periodontally examined.

Non-surgical periodontal therapy (scaling and root planning) was conducted. After four weeks, the results of the initial periodontal treatment were reassessed, and patients were given indication for surgical periodontal therapy in connection with their periodontal status. Of these patients, only those with maximum periodontal pocket depth of 5mms, were further included in the study.

Regarding systemic illness, only patients who declared to suffer from chronic hepatitis C were included in the study. Other systemic conditions such as diabetes mellitus, cardiovascular disease or rheumatoid arthritis were excluded from the study.

The study also included control patients, consisting of patients who were addressed to the department for periodontal examination prior to orthodontic treatment initiation. These patients were not diagnosed with any form of periodontal disease but required maxillary premolar extraction for orthodontic purposes. They were referred to the department of Oral Surgery for tooth extraction and sampling of gingival tissue. Only systemically healthy patients were included in the control group.

After implementing all of the above inclusion and exclusion criteria, three groups of patients were set for the study:

1. P group – 5 patients (3 males, 2 females, age 40-48 years) who were diagnosed with periodontal disease and required periodontal surgery, systemically healthy;

2. PH group – 5 patients (2 males, 3 females, age 36-47 years) who were diagnosed with periodontal disease and required periodontal surgery, chronic hepatitis C;

3. H group – 3 patients (1 male, 2 females, age 32-38 years), who required tooth extraction for orthodontic purpose, periodontally and systemically healthy.

The gingival tissue samples were collected during periodontal surgery (for P and PH groups) or during the extraction of teeth for orthodontic purpose (for H group), from the same area for all patients of the three groups: vestibular marginal gingival of the maxillary premolars. Upon collection, the samples were set in 10% formalin solution for preservation and refrigerated at 8°C. After the collection of the samples was completed, they were transferred to the Department of Histology of the University for Specific Preparation.

The samples were subjected to standard paraffin inclusion and hematoxylin eosin staining. For the immunohistochemical assessment of MMP9, LSAB technique was used with rabbit antibodies (Abcam ab38898, Cambridge, Great Britain). The immunohistochemistry reaction was detected with the Dako EnVision system (DAKO, Glostrup, Denmark). The staining agents

used were 3.3'-Diaminobenzidine (Sigma Chemical Co., Saint Louis, USA) and Mayer hematoxylin. The results of the histological and immunohistochemical processes were observed via optical microscope (Nikon Eclipse 90i, Tokyo, Japan) and relevant pictures of the samples were taken (NIS Elements, Nikon, Tokyo, Japan). A visual quantitative evaluation of the immunohistochemistry reaction was performed and the most important inflammatory morphopathological changes were described. Afterwards, the pictures were assessed with Integrated Optical Density (IOD) analysis, which measured the total color intensity of the immunohistochemistry images, using absolute white and black as reference points. Average IOD values were calculated for each patient group.

RESULTS

The histological assessment of the gingival tissue samples originating from periodontal patients, with/without chronic hepatitis C, exhibited inflammatory changes (tab. I).

TABLE I

Prevalence of histopathological changes

	Group		
Histopathological change	**PH**	**P**	**H**
Acantholysis	80%	80%	33.3%
Orthokeratosis	100%	0%	0%
Papillomatosis	80%	60%	33.33%
Inflammatory infiltrate	100%	100%	0%

All the samples of group PH showed signs of an intense inflammatory reaction. Orthokeratosis was observed within the gingival epithelium, the component cells having elongated nuclei and highly colored chromatin. In addition, acantholysis was observed between the superficial epithelial cellular layers in 80% of the samples, together with an important inflammatory infiltrate. The junction between the epithelial and the connective part of the gingival tissue was affected by papillomatosis, giving a typical wave-like appearance of this area.

Inside the gingival connective tissue, the inflammatory infiltrate, which included granulocytes, lymphocytes and macrophages caused the destructuring of collagen fibers. In some areas, the connective tissue appeared to be fibrotic, showing a damaged extracellular matrix and injured cells with agglutinated chromatin. Furthermore, some blood vessels inside the connective tissue were congested and expressed microhemorrhages (fig. 1, fig. 2).

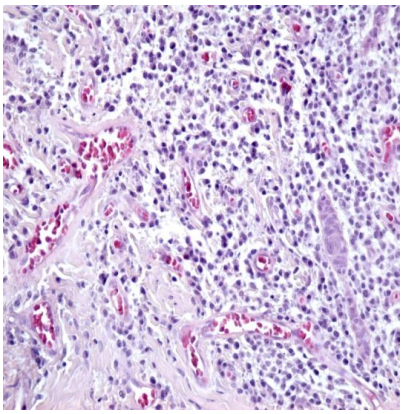

Fig. 1. Gingival tissue sample of PH group (HE staining, x100)

The gingival tissue samples originating from the P group expressed changes in the

normal architecture of the epithelial cellular layers, as a result of the chronic inflammation of the tissues. Acantholysis was observed within the squamous cellular layer due to intense cellular multiplication and immune cell infiltration (80% of the samples in P group).

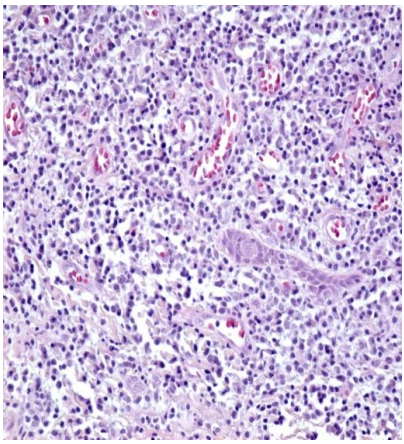

Fig. 2. Gingival tissue sample of PH group (HE staining, x100)

The junction between the epithelium and the connective tissue had a waved shape due to the elongation of the rete pegs, as a sign of papillomatosis (60% of the samples in P group). The inflammatory infiltrate in the connective tissue was moderate, while the blood vessels expressed venous stasis due to the increased osmotic pressure (fig. 3). The gingival samples of the H control group showed few or no signs of histopathological changes, only one of them expressing faint epithelial acantholysis and junctional papillomatosis.

The immunohistochemical assessment of the presence of MMP9 within the gingival samples was positive for the samples of the PH and P groups (tab. II). The PH samples expressed a 50-60% degree of the cellular nuclei coloration, while that of the P samples was lower, around 20-30%. The histological areas which usually expressed a positive reaction were mainly the gingival epithelium and its junction with the underlying corium (fig. 4, fig. 5). The reaction was more positive in the superficial gingival corium for the PH samples and in the gingival epithelium for the P ones. The immunohistochemistry assessment was lowest for samples of the H group.

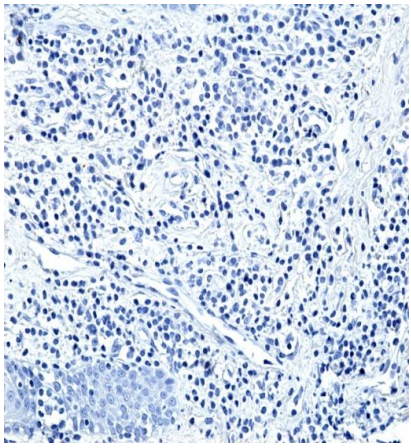

Fig. 3. Gingival tissue sample of P group (HE staining, x100)

The lowest average IOD value was that of the H group, while of the P group was 8.1 times higher and of the PH group 13.6 times more elevated. The average IOD value for the PH group was 1.6 times higher than that of the P group (tab. II).

TABLE II

Prevalence of positive immunohistochemistry reactions for MMP-9 detection and IOD average values

Group	Percentage of positive reaction	Average IOD value (± standard deviation)
PH	50-60%	293 117 ± 112 336
P	20-30%	174 761 ± 84 214
H	< 5%	21 448 ± 7 486

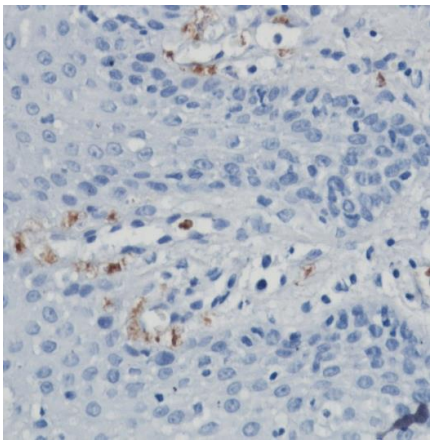

Fig. 4. MMP9 immunohistochemistry positive reaction, PH group sample (x200)

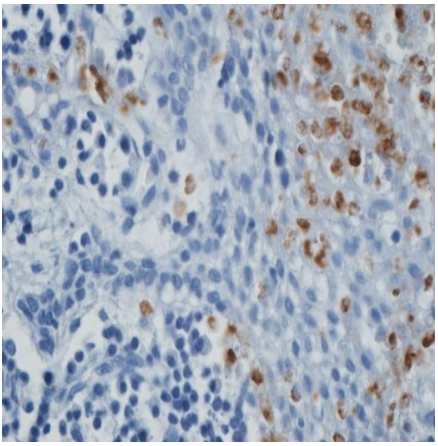

Fig. 5. MMP9 immunohistochemistry positive reaction, P group sample (x200)

DISCUSSION

The histological assessment of the gingival tissue samples revealed the existence of important structural changes caused by the chronic inflammatory reaction in periodontal patients both with chronic hepatitis C and without this systemic disease.

The inflammatory infiltrate affecting the gingival tissue is directly proportional in quantity with the amount of time passed since the debut of the periodontal disease and the systemic conditions of the patient and their type of immune response (5).

In our study, the inflammatory infiltrate was significantly increased in the PH group samples rather than in those of the P group, suggesting that a more intensive inflammatory reaction occurs in such patients.

In the gingival epithelium immune cells like granulocytes and lymphocytes were observed, suggesting an increase in vascular permeability and a decrease in epithelial cell density, due to the dismantling of the hemidesmosome connections (22). Consequently, epithelial acantholysis can occur, as it has been observed in the gingival samples mainly originating from the PH group. This alteration of the normal cellular architecture leads to an epithelial cellular proliferation towards the underlying corium, causing an elongation of the rete pegs (23) The elongated rete pegs, an element of papillomatosis (24), give a characteristic waved shape of the epithelial-corium junction, as it was observed predominantly in the samples of the PH group.

As a result of the inflammatory reaction, the epithelial gingival cells will react by intensifying the keratinization process (25), a type of process which was also observed within the squamous cellular layer of the studied samples. The level of orthokeratosis was higher for the PH group samples than the rest, suggesting a more intensive inflammatory reaction for this group of patients. In addition, the types of cells encountered in more advanced and severe gingival inflammatory reactions as macrophages, lymphocytes and plasmocytes (26) were predominantly observed within the PH group samples, as opposed to the predominantly granulocytes observed within the P group sam-

ples, which are usually found in early, less-severe gingival inflammatory reactions (27).

The proteolytic enzyme, MMP9, especially targets the dissolution of type IV collagen, which is predominantly a component of the basal lamina propria (28). The study delivered similar results, as the immunohistochemistry reaction was particularly positive along the epithelio-connective junction within the P group samples. In patients with chronic periodontitis, MMP9 can also be found in a dispersed manner in both gingival epithelium and corium, in a direct relation with the severity of the disease, as diagnosed by clinical means (29, 30). The samples of the PH group expressed a positive anti-MMP9 reaction in a more increased percentage than the P group samples, suggesting that the inflammatory reaction was more intense for periodontal patients who also suffered from chronic hepatitis C.

MMP9 was found in significantly increased quantities in the blood serum of chronic hepatitis C (31) and it is believed to be involved in the angioneogenesis process that is closely linked to the development of hepatocellular carcinoma, a frequent complication of chronic hepatitis C (32, 33). The prolonged existence of the hepatitis C virus in the hepatic tissues is believed to increase MMP9 production (31), making chronic hepatitis C patients prone to the onset of tissue damaging conditions like periodontal disease.

The immunohistochemistry reaction for MMP9 detection was positive in a significant percentage in the gingival tissue samples of periodontal patients with chronic hepatitis C, in accordance with the enzyme's frequent use as an indicator of hepatic inflammatory status (34, 35, 36). As serum concentration of MMP9 has been noticed to decrease after interferon hepatitis C treatment (37), further studies could address the impact of such therapies on the inflammatory status of periodontal patients with chronic hepatitis C.

CONCLUSIONS

In all, given the limitations of this current study caused by the small number of participating patients, the histological assessment of the gingival samples has revealed that in what concerns the structural pathological changes of the tissue, the periodontal inflammatory reaction is more intensive in patients with chronic hepatitis C than in systemically-healthy periodontal patients. Together with the enhanced expression of MMP9 in such patients' gingival tissue samples, it can be concluded that chronic hepatitis C might have an additional negative impact on the inflammatory status of periodontal patients.

CHILDREN ABDOMINAL HYDATID CYSTS DIAGNOSIS AND TREATMENT. A MULTICENTRIC STUDY (Abstract) : Echinococcosis is one of the most frequent parasitosis and is endemic in Romania. **Material and method** : The data on 111 children with abdominal localization of hydatidosis who underwent exploration and treatment in 3 pediatric surgical clinics were reviewed. The study evaluated 59 patients who were treated at „Sf. Maria" pediatric hospital Iasi during 2004 and 2009, 47 at „Marie Curie" pediatric hospital from Bucharest during 2000 - 2009 and 5 children at Bacău General Hospital 2004-2009. The medical records were reviewed for : demographics, age, gender, location of the cyst, operative procedure, medical treatment, outcome, length of hospital stay and postoperative follow up. **Results** : Age ranged between 2 and 17 years and male/female ratio was 1,1 / 1. 67% of patients lived in rural areas. The liver was the most common organ involved : in 69 cases it was the only organ involved and there were 2 kidney cyst cases, 8 spleens involved, 2 cases in broad ligament, 13 peritoneal cases and 26 cases of cyst located in great omentum. The preferred surgical procedure was Lagrot partial pericystectomy. For medical antihelminthic treatment it was used Albendazole. As complications there were : biliary fistulas, postoperative cholangitis, infection of the residual cavity, anaphylactic reactions. The mortality rate was 0%. **Conclusions** : Most of the patients were from rural area. The liver was the major organ involved. The treatment includes both surgical and medical means. There is a relatively high rate of postoperative complications (although some of them being minor) in 31 patients. **Key words :** ABDOMINAL HYDATID DISEASE, SPLENECTOMY, PERY-CYSTECTOMY, LAPAROSCOPY

Echinococoza este o boală parazitară cronică şi complexa cu distribuţie cosmopolita cauzata de larvele de *Echinococcus granulosus* şi care cel mai frecvent afectează ficatul şi plămânii, chiştii hidatici cu alte localizări se întâlnesc relativ mai rar totuşi ei putând fi întâlniţi în orice organ şi ţesut (6,7). Prezentul studiu vine sa confirme aceste lucruri fiind totodată în concordanţa cu datele din literatură ficatul fiind cel mai afectat organ urmat de epiplon, peritoneu, splina, rinichi, ligamentul larg. Scopul acestui studiu este de a documenta evoluţia clinică, datele epidemiologice, modalităţile de diagnostic şi tratament, evoluţia postoperatorie a cazurilor tratate chirurgical şi evoluţia celor tratate medical.

MATERIAL ŞI METODĂ

Locaţia studiului

Pacienţii cuprinşi în lotul de studiu provin din 3 servicii de chirurgie pediatrică :

- Clinica de Chirurgie pediatrică a Spitalului de copii „Sf. Maria" Iaşi, unde au fost diagnosticaţi şi trataţi un număr de 59 de pacienţi distribuiţi pe un interval temporal de 5 ani, respectiv 2004 - 2009, ceea ce a permis realizarea unui studiu prospectiv ;
- Clinica de Chirurgie pediatrică „Marie Curie" Bucureşti, unde au fost diagnosticaţi şi trataţi un număr de 47 de pacienţi distribuiţi în două perioade temporale :
- 2000 - 2004 interval temporal care a permis efectuarea unui studiu retrospectiv ;
- 2004-2009 interval temporal care a permis efectuarea unui studiu prospectiv.
- Serviciu de Chirurgie pediatrică al Spitalului Judeţean Bacău unde au fost diagnosticaţi şi trataţi un număr de 5 pacienţi distribuiţi într-o perioadă temporală cuprinsă pe parcursul a 4 ani 2004 - 2009, ceea ce a permis elaborarea unui studiu prospectiv.

REZULTATE ŞI DISCUŢII

Analiza distribuţiei pacienţilor în funcţie de vârstă şi de apartenenţa la centrele în care s-a efectuat cercetarea este redată în tabelul I

După localizare am identificat următoarea repartizare a cazurilor :

Parametrii sanguini

Hipereozinofilia a fost prezentă la 47 de pacienţi, iar leucocitoza la 31,53% din cazuri.

Un număr redus de pacienţi a prezentat leucopenie (5 cazuri).

VSH a fost crescut în majoritatea cazurilor, dar am identificat pacienţi la care constantele biochimice se încadrau în limite normale.

Dintre pacienţii cu chist hidatic hepatic (101 cazuri), 8 cazuri au prezentat hiperbilirubinemie, iar în 5 cazuri s-au identificat alterări ale funcţiei hepatice (valori anormale ale TGO şi TGP).

TABELUL I

Vârsta pacienţilor funcţie de centrul în care s-a efectuat studiul

	Vârsta minimă (ani)	Vârsta maximă (ani)	Vârsta medie (ani)
Iaşi	2	17	12,18
Bucureşti	3	16	10,72
Bacău	5	14	9,35
Nr. total	2	17	11,51

Parametrii serologici

Testele serologice (ELISA) au fost efectuate în 25 de cazuri, cu o rată a rezultatelor pozitive de 96%.

Toate cazurile cu pozitivitatea testelor serologice au fost confirmate prin rezultatele intervenţiei chirurgicale.

Examenul ecografic

Încadrarea chisturilor hidatice hepatice s-a făcut conform clasificării Gharbi (7) :

- tip I colecţie lichidiana pura - 45 chisturi
- tip II colecţie lichidiana cu perete dehiscent - 71 chisturi
- tip III colecţie lichidiana cu septuri - 68 chisturi
- tip IV chist cu ecouri heterogene - 14 chisturi
- tip V chist cu perete gros reflectogen - 7 chisturi

Examenul tomografic computerizat - a confirmat prezenta celor 205 chisturi cu localizare hepatica si in plus a permis o mai buna precizare a raporturilor chisturilor cu structurile vasculare biliare si organele de

TABELUL II

Cazurile de chist cu localizare hepatică şi pluriorganică

Chisturi hepatice	69
Hepatice + splenice	4
Hepatice + renale	1
Hepatice + epiplonice	15
Hepatice + peritoneale	4
Hepatice + ligamentul larg	1
Hepatice + splenice+ peritoneale+ epiplonice	2
Hepatice +peritoneale +epiplonice	5

vecinătate.

Tratamentul medical – din cei 111 pacienţi cuprinşi in studiu 71 au urmat tratament cu albendazol anterior intervenţiei chirurgicale (63,96%) 10 mg/kg/zi iar 102 pacienţi (91,89%) au fost supuşi acestui tratament după intervenţia chirurgicala timp de 2 săptămâni până la 2 luni. In 5 cazuri diagnosticul ecografic a specificat prezenta de chisturi hepatice localizate central care au necesitat administrare de Albendazol. Din acestea 4 au prezentat in cursul urmăririi ecografice semne de degenerare arătând eficiente tratamentului in timp ce unul s-a mărit exteriorizându-se si care a fost operat.

Tratamentul chirurgical

Pacienţii cuprinşi în lotul de studiu au fost împărţiţi în funcţie de metoda terapeutică, chirurgicală, în:

- pacienţi care au urmat tratament chirurgical clasic (95 cazuri);
- pacienţi care au urmat tratament laparoscopic (16 cazuri);
- pacienţi care au urmat tratament laparoscopic convertit în chirurgie deschisă (8 cazuri).

Tratamentul chirurgical clasic – a fost metoda terapeutica utilizata in cazul a 95 de pacienţi ca prima metoda si in 8 cazuri fiind vorba de conversia intervenţiei laparoscopice. Ca modalitate de abord s-au folosit:

- laparotomia mediana
  - supra şi subombilicală - 50 cazuri
  - supraombilicală - 19 cazuri
  - subombilicală - 5 cazuri
- abord subcostal drept – 20 cazuri
- toraco-freno-laparotomie - 9 cazuri

Obiectivele tratamentului chirurgical în cazul chistului hidatic indiferent de metoda folosita sunt aceleaşi : inactivarea şi indepartarea parazitului în condiţii de izolare perfecta a cavitaţii peritoneale, tratarea cavitaţii reziduale hepatice, tratarea complicaţiilor biliare.

Pentru inactivarea parazitului s-au folosit:

TABELUL III

Cazurile de chist cu localizare unică abdominală extrahepatică

Chisturi renale	1
Chisturi splenice	2
Chisturi epiplonice	4
Chisturi peritoneale	2
Chisturi in ligamentul larg	1

TABELUL IV

Complicaţiile capitonajului

	Nr. cazuri
Abces	1
Colangită	0
Fistulă biliară	3
Recurenţă	1

TABELUL V

Complicaţiile omentoplastiei

	Nr. cazuri
Abces	3
Colangită	1
Fistulă biliară	4
Recurenţă	3

- ser hiperton Na – Cl 20% - 53 cazuri
- alcool absolut 70-95% - 19 cazuri
- apă oxigenată - 13 cazuri
- metronidazol - 11 cazuri
- cetrimide - 5 cazuri

Ca interventii chirurgicale s-au practicat:

- perichistectomie parţiala Lagrot - 89 pacienţi cu chist hidatic hepatic
- perichistectomie ideala (totala, în cazul chisturilor marginale) - 9 pacienţi
- segmentectomie (în cazul lobului hepatic stâng complet distrus) -3 cazuri
- splenectomie - 6 cazuri, restul de 2 chişti splenici fiind trataţi prin perichistectomie parţială
- în cazul chisturilor hidatice renale s-a practicat perichistectomie parţiala într-un caz şi nefrectomie în celalalt
- chisturile localizate în epiplon şi peritoneu au fost extirpate complet.

În ceea ce priveşte cavitatea restanta s-au practicat următoarele metode:

- capitonajul - 36 cazuri
- marsupializarea cu drenaj extern pe sonda Foley - 11 cazuri

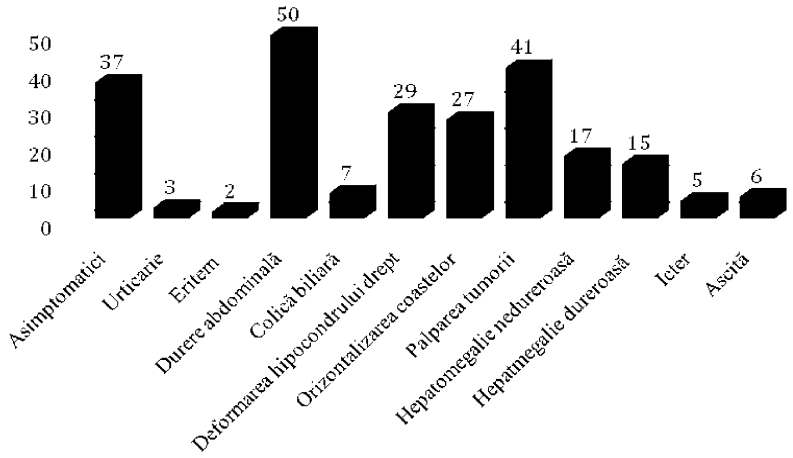

Fig. 1. Simptomele clinice ale pacienţilor care au prezentat chisturi hidatice hepatice cu localizare mono şi pluriorganică

- omentoplastia - 25 cazuri
- drenaj extern - 76 cazuri
- drenaj intern chisto-digestiv - 2 cazuri

Metoda laparoscopică nu a fost utilizata decât la Bucureşti studiul pe acest lot începând în anul 2004. Conversia în intervenţie clasica a fost necesara în 8 cazuri din următoarele motive : localizarea chistului (în domul hepatic) - 3 cazuri, complexitatea leziunii – 2 cazuri, incidente intraoperatorii (hemoragie) 2 cazuri, examen imagistic irelevant - un caz. Deşi pare mare aceasta rata de conversie ea reflecta debutul ca modalitate de tratament a chistului hidatic a laparoscopiei în chirurgia pediatrica.

Intervenţia chirurgicală clasică a durat în medie 75 minute, cu valori cuprinse între 35 şi 165 de minute.

Intervenţia laparoscopică a durat în medie 115 minute, cu valori cuprinse între 65 -160 de minute.

Se constată că durata medie a intervenţiei clasice a fost mai mică decât a celei laparoscopice. Acest lucru poate fi explicat prin faptul că în momentul efectuării studiului laparoscopia era o metodă nou introdusă în România, motiv pentru care chirurgii se aflau în perioada curbei ascendente de învăţare ceea ce a crescut semnificativ durata intervenţiei.

Complicaţii postoperatorii pot fi împărţite în complicaţii ale intervenţiei chirurgicale propriu-zise care apar în cursul intervenţiei, şi complicaţii postoperatorii la distanţă.

Complicaţiile în cazurile tratate prin metoda Lagrot au asociat :

- Abces în cavitatea reziduală – 2 cazuri
- Colangită – 2 cazuri
- Fistulă biliară – 9 cazuri care au avut evoluţii lente, pe o perioadă cuprinsă între 4-8 săptămâni,

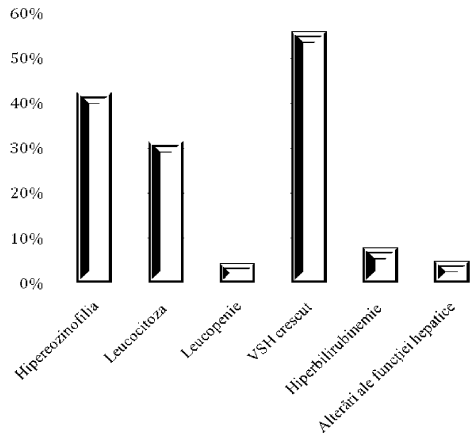

Fig. 2. Repartiţia pacienţilor funcţie de rezultatele investigaţiilor de laborator

- Recurenţă – 6 cazuri

Prezenţa acestor complicaţii a crescut durata de spitalizare la 14,7 zile modificând implicit costurile aferente.

În ceea ce priveşte complicaţiile capitonajului acestea sunt redate în tabelul IV.

Durata media a zilelor de spitalizare în cazul pacienţilor care au prezentat complicaţii ale capitonajului a fost de 12,2.

Durata media a zilelor de spitalizare în cazul pacienţilor care au prezentat complicaţii ale omentoplastiei a fost de 12,2. Se constată prin analiza comparativă a complicaţiilor capitonajului *versus* omentoplastie că numărul de abcese respectiv recurenţa afecţiunii a fost mai mare în cazul omentoplastiei.

CONCLUZII

Tratamentul bolii hidatice hepatice încă nu este codificat şi aceasta pentru că nu există o tehnică perfectă, aplicabilă într-o anumită situaţie şi ale cărei rezultate să fie întotdeauna aceleaşi, iar boala hidatică este deosebit de poliformă atât ca localizare cât şi ca modificări anatomo-patologice.

Între argumente şi contraargumente, chirurgul trebuie să aibă capacitatea de a adapta fiecărui caz varianta tehnică cea mai potrivită, urmărind evitarea complicaţiilor postoperatorii, fără a pune inutil în pericol viaţa pacientului.

Experienţa ne demonstrează că fiecare metodă terapeutică, chirurgicală şi/sau medicală trebuie adaptată stării generale a pacienţilor, activităţii şi etapei evolutive a infecţiei parazitare, poziţiei şi extensiei chisturilor hidatice şi nu în ultimul rând experienţei chirurgului terapeut.

THE INFORMED CONSENT IN PEDIATRICS-A CHILD'S RIGHT (Abstract): Consent signifies the patient's knowingly authorization of a medical intervention. Revealing the truth about the patient's condition refers to the provision of information by the physician regarding the diagnosis and the treatment, as well as their understanding by the patient. His or her decision-making capacity refers to the ability of understanding the data that have been provided. The independent decision refers to the patient's right to make a free decision regarding his or her treatment, without constraint or manipulation. Informed consent is one of the most sensitive issues of the physician-patient, researcher-subject relationship. Minors do not have the capacity of independent decision; therefore, the decision by substitution given by parents or legal representatives is required. The minor child's consent to the medical treatment and pediatric scientific research expresses itself under the form of assent, which is valid starting with the age of 14. Doctors should ask for parental consent before medical interventions (except in cases of emergency, when parents cannot be contacted). From a practical standpoint, when it comes to obtaining a valid consent, it is useful to make a distinction between the problem-solving process and the decision-making process. The permission given by parents includes all standard elements of informed consent. In each case, the doctor has to make sure that he or she has a valid consent because, in legal terms, treating a patient without his or her consent is a crime, while treatment based on inadequate consent constitutes negligence. **Keywords:** INFORMED CONSENT, DECISION MAKING, PEDIATRIC MEDICAL CARE.

THE HISTORICAL ASPECTS

The consent represents the informed authorization regarding the medical intervention made by a patient (1). Revealing the truth about the patient's condition refers to the provision of information by the physician regarding the diagnosis and the treatment, as well as their understanding by the patient. His or her decision-making capacity refers to the ability of understanding the data that have been provided (2). The independent decision refers to the patient's right to make a free decision regarding his or her treatment, without constraint or manipulation. The first "Save the Children" organization was founded in London in 1919 by Englatyne Jebb, who made the decision to try to save and also to improve the lives of children around the world; thus, her aim was to establish an international organization

capable of intervening in areas where child protection was not applied, and where children's rights were not respected (1). Promoting children's rights was a movement that began in 1924 at the time of the adoption of the Declaration of the Rights of the Child by the League of United Nations, which refers to the fact that the child must be protected against any form of exploitation, that he or she has the right to the means necessary for his or her material as well as spiritual normal development, that orphans and widows should be protected (2, 3).

Unfortunately, the 1924 Geneva Declaration on the Rights of the Child was not enforceable under international law; instead, it constituted a guide for the member countries. Thus, fighting hunger and providing care to children were the main concerns. Englantyne Jebb designed and facilitated the adoption of the Declaration of the Rights of the Child by the League of Nations (now the United Nations), which represents the first international document where "the child's rights" are mentioned and promoted in a unitary manner, and where the child's protection is implicit (3, 4). This Declaration, with its extended form in 1959, is the source of inspiration used in drafting the United Nations' Convention on the Rights of the Child adopted by the United Nations General Assembly on November 20th, 1989 (4, 5). The Convention consists in 54 articles that address the basic needs of children anywhere in the world: the right to live, the right to develop to their full potential, the right to be protected from harmful influences, the right to be protected from abuse and exploitation and the right to fully participate in the familial, cultural and social life (5, 6). The four core principles of the Convention are non-discrimination, devotion to the child's best interests, the right to life, survival and development and the respect for the child's points of view (5, 7). According to the Convention, a child is defined as *"[...] every human being below the age of 18 years unless, under the law applicable to the child, majority is attained earlier*". Any State which signs the Convention acknowledges its content, undertaking to respect and apply it properly. So far, the Convention has been adopted by 193 countries, members of the United Nations, except the USA and Somalia. In the late 60s, the focus was on the participation rights of the child, as several opinion leaders claimed that underage youngsters were able to make decisions on important issues in their lives and that they should be allowed to participate in making these decisions (6, 8).

The Law in British Columbia and New Brunswick increase pediatricians' accountability and state that a child can consent to health care. The consent of the minor is sufficient and effective, and physicians do not need the written consent of the parent or of the legal guardian of the child, if the pediatrician is sure that the underage patient understands the benefits and the risks associated with the treatment (4, 9). The pediatrician should consider the medical interests of the child, which includes the lack of distress, the restoration of the body functions and the physical health (8, 10). Children aged over 10 years old are held responsible in court, as the "doli incapax" principle was abolished in 1998. However, minors do not have the rights the adults benefit from; therefore, what is actually targeted is the autonomy that should be the same for everyone, because it is a rule about how everyone

around should be treated (11). Eekelaar proposed a periodic assessment of children, in order to understand exactly the child's interests and desires, and to reconcile them with their autonomy. Unfortunately, there are many constraints such as parents' divorce, the custody, communication difficulties, abuse, neglect, various diseases; they all decrease children's decision-making ability and distort their real desires. The "Rule of seven"' defines a child as incompetent until he is 7 years of age; the child is generally incompetent, with some exceptions, before the age of 14 years old; the child is considered to be competent, with some exceptions, between 14 to 21 years old (8, 12). In the State of Ontario, it is considered that a sane person, of any age, can decide on their own medical treatment. Health Care Consent Act does not allow that the treatment should be administered to any person able to make their own decisions, regardless of age, without their consent. The consent of the parent or of the guardian is required if the minor is unable to make decisions because of the nature of their illness. The Law in Manitoba, Newfoundland and Labrador state that minors under 16 are legally incapable of decision making. New Brunswick, Quebec and British Columbia allow capable minors to decide on their own treatment. The Constitution acknowledges that each person, adult or mature minor has the right to accept or to reject the suggested investigations and / or treatment (11, 13).

The Convention on the Rights of the Child

In 1978, a year before the International Year of the Child, the Polish Government proposed elaborating a *Convention on the Rights of the Child*. A special working group was founded that had to draw up a draft of the Convention. On September 2nd, 1990, the Convention became international law; it consists of 54 articles that address the basic needs of children everywhere, such as the right to live, the right to develop to their full potential, the right to be protected from abuse, exploitation and harmful influences, and the right to fully participate in the familial, cultural and social life (5, 14). The four core principles of the Convention are non-discrimination, devotion to the child's best interests, the right to life, survival and development and the respect for the child's points of view. According to the Convention, children should be treated with respect, and the state is obliged to ensure the best conditions for their development, to respect their rights and protection norms; the Rights of the Child need to apply to all minors without discrimination. Thus, every child has the right to life, education and harmonious development (9, 15).

The United Nations, in the Universal Declaration of Human Rights and in the International Covenants on the same subject, proclaimed and agreed that everyone is entitled to all the rights and freedoms set forth therein, without distinction of any kind, such as race, color, sex, language, religion, political or other opinion, national or social origin, property, birth or other status. In the same Declaration, the United Nations recognized the right of children to receive special care and assistance, with the conviction that the family, as the fundamental unit of society and the natural environment for the growth and the well-being of all its members (especially children),

should benefit from the necessary protection so that it can fully assume its responsibilities within the society. For the full and harmonious development of his or her personality, the child should grow up in a family environment, in an atmosphere of stability, love and understanding (6, 13). A child should be fully prepared to live an individual life in society and be brought up in the spirit of the ideals proclaimed in the Charter of the United Nations, with an emphasis on dignity, freedom, tolerance, equality and solidarity. The need to extend the particular care given to the child has been stated in the Geneva Declaration on the Rights of the Child of 1924 and in the Declaration of the Rights of the Child adopted by the General Assembly on November 20th, 1959 (12, 15). It has also been recognized in the Universal Declaration of Human Rights, in the International Covenant on Civil and Political Rights (articles 23 and 24), in the International Covenant on Economic, Social and Cultural Rights (article 10) and in the statutes and applicable instruments of specialized agencies and of international organizations concerned with the child's welfare ("Given his or her lack of physical and mental immaturity, the child needs special safeguards and care, including appropriate legal protection, before as well as after birth" – the Declaration of the Rights of the Child) (3, 9, 16). The Convention on the Rights of the Child incorporates, more than any other document, the full spectrum of human rights (civil, political, economic, social and cultural) in order to ensure the full development potential of children, in an atmosphere of freedom, dignity and justice. The Convention defines children's rights in a complex manner.

Aspects from Romania

Romania ratified the Convention on September 28th, 1990 by Law No. 18/1990 (published in the *Monitorul Oficial* No. 314 of June 13th, 2001) and was inspired by it when drafting the Law No. 272/2004 on the protection and the promotion of the child's rights. The first Romanian law on child's protection was passed in 1970 (Law No. 3/1970) (11, 16). The National Authority for the Protection of the Child and the Ministry of Education, the Ministry of Labor, Social Solidarity and Family, the Ministry of Health as well as the other related public and private institutions will provide initial and ongoing training of the staff who, while performing their duties, come into contact with the protection and the promotion of the child's rights (article. 143 paragraph 3 of Law No. 272/2004 on the protection and the promotion of the child's rights). Before 1989, the informed consent did not apply to the Romanian medicine.

During the communist period, the paternalism was promoted in the doctor-patient relationship (the former used to decide on the therapy which suited the patient best, while research did not involve informing the patient included in the study) (6, 11, 13). The small number of specialists in the field of bioethics, together with the lack of clear norms regarding the implementation of the patient's informed consent go hand in hand with the lack of education of healthcare professionals in this field, of researchers performing clinical studies and, last but not least, of the population requiring medical attention. If the patient's decision-making capacity or consciousness is temporarily or permanently affected or if the patient is underage, the decision-making responsibility is transferred to the patient's legal representa-

tive or to a panel of arbitrators (8, 13, 17).

A particular issue – the vulnerable patients

The thirteenth principle of the *International Ethical Guidelines for Biomedical Research involving human subjects 2002* defines vulnerable individuals as being "relatively or totally incapable of protecting their own interests. Furthermore, these individuals might have insufficient strength, intelligence, education, resources and other attributes necessary to protect their own interest" (2, 4, 10). The Informed Consent targets both patients and healthy subjects (experiments-research). In February 1931, the government in Weimar (Germany) prohibits "Any experiment if consent is not obtained after all the explanations have been provided" (3, 10).

Mikhail Bulgakov, Russian physician and writer recalls in his book, "Stories of a young doctor", several events which took place from 1917 to 1918 and in which the question of consent arose, including the case of a young girl suffering from diphtheria croup, when tracheotomy was not done before the mother gave her consent (5, 17). A study conducted in Denmark in the period 1960-1994 highlights the reasons why there is no such thing as true informed consent: people are suffering, so they cannot think as they normally would in other situation, the patient is afraid, physicians and / or researchers do not provide information about side effects, they minimize them intentionally or unintentionally or they do not give explanations in a way that patients can understand them (9, 18).

In 1964, "The World Medical Association" adopted the Declaration of Helsinki - "Helsinki I". This includes ethical rules of experimentation on humans and principles of informed consent; thus, the document states the purposes of the study, the methodology, the expected results, the possible side effects, the risks for the patient (7, 12). The patient must be informed orally and in writing. In 1975, the "Helsinki II" Declaration was adopted in Tokyo; this document states that, in certain circumstances, it is possible to waive informed consent (10, 17).

After 15 years from the adoption of the Declaration of Helsinki II, the Danish Ethics Committee decided that everyone should have the right to informed consent. In 1994, the Amsterdam Declaration is issued, which, among others, also comprises information on the informed consent of vulnerable individuals (children, elderly people, mentally ill people). At the International Conference of Medical Orders 1987 the following is stated: "Apart from emergencies, the physician must explain the effects and the consequences of a treatment to the patient". The informed consent can be achieved in three ways: a) orally - in the presence of the medical personnel, b) in writing, c) by means of video recording, with witnesses from outside the medical facility (11, 12, 13). When the patient is unable to express their will and an emergency medical intervention is required, the medical personnel is entitled to infer the patient's consent from a previous expression of his or her will (6, 16). If the patient requires an emergency medical intervention, their legal representative's consent is not required; when their legal representative's consent is required, the patient must be involved in decision-making process as far as their ability to understand allows them to. If health care providers believe that the intervention is in the patient's best

interest and the legal representative refuses to give his or her consent, the decision becomes the responsibility of a specialized panel of arbitrators, which is made of three doctors for the patients admitted to hospital and of two doctors for outpatients. In addition, the patient's consent is required for his or her participation in clinical medical education and scientific research. The individuals who are not able to express their will cannot be subjects in scientific research unless consent is obtained from their legal representative and if the research is done in the interest of the patient. It is not allowed to use photos or films of the patients in a medical facility without their consent or the consent of their legal guardians unless the images are necessary to establish a diagnosis or a treatment and to avoid suspicion of malpractice (14, 16).

The Declaration for promoting Patients' Rights in Europe, issued at the European Consultation on the Rights of Patients (15, 17) refers to the informed consent in detail, with clear information on vulnerable people. Patients should be given explanations using plain language about the steps to be taken, about diagnosis, treatment approaches and about the existence and the nature of the implied risks (9, 13). Thus, the European countries have developed their own documents. In Romania, these issues were enacted in 2003 when law 46 was published – the Patient's Rights Law (*Law No. 46/2003 – Monitorul Oficial 2003*). Under this law, any medical act must be carried out with the informed consent of the patient or of his or her legal representative; some believe that parents or guardians have the right to give consent "by substitution" for underage patients. By the early twentieth century, children had been regarded as the property of parents, the latter having the decision-making right on behalf of the underage individual. The child is an independent being, not a miniature adult (16, 18). A child differs from an adult by anatomical, physiological and psychological characteristics and is defined as any human being below the age of 18 years unless, under the law applicable to the child, majority is attained earlier. American Laws designate two cases in which underage individuals have the authority to make decisions regarding their health (8, 17): they are self-sufficient, they are married, they have children, they belong to the military or, on their own initiative, require medical treatment for certain diseases or conditions (sexually transmitted diseases, pregnancy, abuse / dependence on alcohol and drugs (emancipated minor) (9, 18). Competence and mental capacity in the medical context acquire distinct meanings. Competence is a legal term that signifies the legal authority in the management of particular situations, in a particular area of life, while mental capacity refers to the cognitive, perceptual and communicative ability to perform a particular task (3, 11, 19).

The decision-making ability can be determined by reference to the ability to make a choice, to understand relevant information, to appreciate the consequences of decisions and to the ability to manage information rationally. Patients with decision-making capacity should be included in the informed consent process, regardless of their level of competence (5, 19). The understanding capacity refers to the process by which the patient engages constantly in understanding the diagnosis and the therapeutic alternatives.

The American Academy of Pediatrics argued that "the whole doctrine" of the informed consent has a particular applica-

tion in pediatrics (5, 11). Research involving children is permissible only if it is done with therapeutic purposes to benefit the subjects and with the consent of parents or of legal guardians; it should be accompanied by the older child's approval, thus respecting the principle of patient autonomy and having the approval of competent ethics committees (when the child is able to understand correctly and fully, his or her consent is necessary, together with that of his or her legal representative) (13, 18). Non-therapeutic experiments on children are not accepted, except for situations where the use of an experimental drug is the last chance to save the life of that particular underage patient. Research of any kind on institutionalized subjects is not advisable and it requires special regulations. Most institutionalized subjects integrate in the concept of paternalism, rejecting autonomy (11, 13, 19).

There is a provision in Article 4 of the Charter of Hospitalized Children developed by UNESCO which stipulates their right to be informed, in a manner that should be appropriate to his age. Both the physician and the parents must be involved in the informing process (4, 7, 11); this attitude explains itself psychologically by the fact that the anguish of silence can induce discomfort to the child. Until the age of 4, the child is scared of the medical act; between 4-8 years of age, curiosity leads the child to accept medical procedures; after 8 years of age, the child will participate actively in performing therapeutic procedures (9). The UN Convention on children's rights-New York,1991-expressly provides that "Member States shall ensure the child who is capable of discerning the right to express their views freely on all matters which affect them, and their opinion will be taken into consideration according to their age and maturity".

CONCLUSIONS

The capacity to consent always requires the ability to understand the implications of the decisions as well as to evaluate in a rational manner the consequences of those decisions. Frequently, the doctor struggles alone with a medical ethical decision-making pressure, without any legal protection and with important professional, psychological and social implications.

The society has the ability to provide consent through its institutions for those particular cases where the consent cannot be given by the parents or the legal guardians, except for the emergency situations when the doctor is authorized to decide the most appropriate approach in order to preserve life.

Until 10 years ago in Romania there was no legislation that specifically dealt with child protection in the process of scientific research. In the case of underage individuals, there is no mention about a specific age beyond which consent is mandatory and the doctors should ask for parental consent before medical. The permission given by the parents includes all standard elements of informed consent. The authorization granted by the underage individual may be revoked at any time by another competent authority on the child best interest.

From a practical standpoint, a valid consent requires to make a distinction between the problem-solving process and the decision-making process. The doctor has to make sure that the subject consent is valid because, in legal terms, treating a patient without his or her consent is a crime, while treatment based on inadequate consent is negligence.

RELATIONSHIP BETWEEN IDIOPATHIC SCOLIOSIS AND FACIAL ASYMMETRY IN YOUNG PATIENTS (Abstract): This study aims to evaluate the relationship between idiopathic scoliosis and facial asymmetry, on a sample of young patients. **Material and methods:** 17 orthopedic patients (1 boy and 16 girls) aged 15-28 years (mean age 20.06±4.575 years) admitted to Medical Rehabilitation Centers in the northeastern region of Romania (Iasi and Bacau cities) between January 2014 and April 2015 were assessed. Orthopedic data were extracted from medical records and radiological examinations, and orthodontic data were obtained from physical and photostatic examinations. Statistical evaluation was performed using *SPSS 16.0* software. **Results:** All patients were diagnosed with idiopathic scoliosis at puberty. Cobb angle of the main spinal curvature was ≤20° in 35.3% of patients, 20-40°(45°) in 17.6% of patients and ≥40°(45°) in 47.1% of patients. Convexity of the major curve was to the right in 88.2% of patients and to the left in 11.8% of patients. 58.8% patients underwent orthopedic treatments and 41.2% surgical treatments. All orthopedic patients presented facial asymmetry (right/left and overall/lower face) and lateral deviation of the head (right/left and mild/moderate). Only 52.9% of patients had malocclusions, patients who underwent orthopedic treatments. We found statistically significant correlations between scoliosis severity and head deviation, malocclusions, Angle classes and anomalies types; between the direction of convexity of the major curve and the types of facial asymmetries; and between types of scoliosis treatments and types of facial asymmetries, malocclusions, Angle classes and types of anomalies ($p<0.05$). **Conclusions:** Our study found in young patients a relationship between idiopathic scoliosis and facial asymmetry. **Keywords:** IDIOPATHIC SCOLIOSIS, FACIAL ASYMMETRY, MALOCCLUSIONS, BODY POSTURE.

Scoliosis is a three-dimensional deformation of the spinal column, defined as a lateral deviation greater than 10 degrees in frontal plane, associated with axial rotation, located at the cervical, thoracic and/or lumbar level (1, 2). There are several different types of scoliosis: congenital, neuromuscular and idiopathic. Idiopathic scoliosis is the most common type of scoliosis and has a multifactorial etiology (genetic predisposition, metabolic, hormonal and biomechanical factors). It can appear at any age and is more common in teenage girls, 90% of cases presenting a right-sided thoracic curve. The prevalence of adolescent idiopathic scoliosis is between 0.47% and 5.2% (3).

The diagnosis of idiopathic scoliosis is made by history, physical and radiographic examination. Postero-anterior X-ray view of the spinal column determines the degree of

severity of spinal curvature by the Cobb method (4). Idiopathic scoliosis is a progressive disease with aesthetic (important asymmetry) and functional consequences (cardiac and respiratory dysfunctions). It requires clinical observation over time to assess the risk of curve progression. Orthopedic treatment (kineto-physiotherapy, braces) does not correct scoliosis, but prevents its progression during the growth period of the patient. The goal of surgical treatment is to restore and maintain alignment, being indicated when the curve exceeds 40 degrees (3, 5).

The perfect bilateral symmetry of the face and the body is rare due to biological variation, being a theoretical concept. Right-left differences are due to functional and morphological asymmetries (6, 7). Slight, invisible, subclinical facial asymmetry is relatively common, being defined as the difference in size between the right and left sides of the face, observed only by the method of composite face photo (8, 9). Severe facial asymmetry occurs in craniofacial syndromes. Asymmetry affects the lower face (lips, chin) more frequently than the middle (nasal pyramid, orbits) and upper face (12). According to transverse discrepancies, facial asymmetry is classified as dental, skeletal, functional and muscular (10). Clinical features are polymorphic, depending on etiopathogenesis. Clinical and radiological diagnostic procedures aim to identify the causal factor, location and affected tissue. However, clinical examination remains the most important diagnostic tool for facial asymmetry (11).

The interest in finding the relationship between idiopathic scoliosis and facial asymmetry is 50-year-old, being based on the hypothesis of the anatomical and functional relation between the dento-maxillo-facial complex and the spinal column. The results of observational and case-control studies and case reports were inconclusive, and a cause-effect relationship was not found. Some cephalometric studies investigating relationships with posture have mentioned a correlation between facial morphology and head inclination in relation to the spinal column and vertical plane (12).

Our study aimed to investigate the relationship between idiopathic scoliosis and facial asymmetry in a sample of young patients treated in rehabilitation centers, to find the correlations between the characteristics of idiopathic scoliosis and facial asymmetry, and the coexistence of malocclusions in young orthopedic patients.

MATERIAL AND METHODS

We conducted a review of patients with idiopathic scoliosis admitted and treated in Medical Rehabilitation Centers in the Iasi and Bacau cities in northeastern Romania from January 2014 to April 2015. A total of 17 patients, 1 (5.9%) male and 16 (94.1%) females, aged 15-28 years (mean age 20.06 ± 4.575 years), with idiopathic scoliosis were identified. Informed consent was obtained from all patients. Included were only young patients (adolescents and young adults) who had clinical and radiological evidence of lateral spinal curvature and were diagnosed with idiopathic scoliosis. Patients with other spinal conditions, genetic or endocrine syndromes, as well as adults over 30 years of age or those who refused orthodontic examination were excluded from the study.

The following data from the medical records and spinal radiographs of the patients with idiopathic scoliosis included in the study were collected and analyzed: medical history, clinical signs, scoliosis localization, convexity of the spine, Cobb angle, type of treatment and post-treatment out-

comes. The patients were examined clinically and photo statically by the orthodontist in order to establish facial asymmetry by extra-oral examination of the face and head posture; presence/absence of malocclusions (Angle classes, malocclusion and sagittal, transverse or vertical inter-arches asymmetry) by examining the dental arches and occlusion.

Statistical analysis was performed using *SPSS 16.0* software (Chicago, Illinois, USA) for Windows. The data were characterized by descriptive statistics and contingency tables, using the *Pearson Chi-square test* (χ^2). Any *p* value less than 0.05 was interpreted as statistically significant.

RESULTS

According to their medical history, all patients were diagnosed with idiopathic scoliosis at puberty, at the age of 13 to 15 years old. Patients had clinical signs of scoliosis: lateral deviation of the head, shoulder asymmetry, winged scapula (right/left), waist angle deformity (difference between right/left waist angles), hip asymmetry, lateral deviation in frontal plane of the spinal column when the trunk is bent forwards with the occurrence of gibbosity on the side of the convexity of the curve.

The lateral curve of the spinal column was unique ("C" shaped) at cervical level in 2 (11.8%) patients, thoracic level in 9 (52.9%) patients and lumbar level in 1 (5.9%) patient or double ("S" shaped) at the cervicothoracic level in 1 (5.9%) patient and thoracolumbar level in 4 (23.5%) patients. The Cobb angle measured on the postero-anterior spine radiograph was ≤20° in 6 (35.3%) patients, between 20-40°(45°) in 3 (17.6%) patients and ≥40°(45°) in 8 (47.1%) patients. Convexity of the major spinal curve was on the right side in 15 (88.2%) patients and left side in 2 (11.8%) patients. Progression of scoliosis was stopped by orthopedic treatments(kineto-physiotherapy, Milwaukee, Cheneau, Boston braces) in 10 (58.8%) patients and surgical treatments in 7 (41.2%) patients. Post-treatment outcomes were favorable.

Asymmetry of the two hemifaces was established according to the facial midsagittal plane, right hemiface being more developed in 9 (52.9%) patients and the left hemiface in 8 (47.1%) patients. Also, 11 (64.7%) patients had overall facial asymmetry and 6 (35.3%) patients lower face asymmetry. Head inclination was to the right side in 10 (58.8%) patients and to the left side in 7 (41.2%) patients. Also, 10 (58.8%) patients had mild head deviation and 7 (41.2%) patients moderate head deviation. Only 9 (52.9%) patients had malocclusions: 4 (23.5%) patients Angle Class I, 1 (5.9%) patient Angle Class II and 4 (23.5%) patients Angle Class III, associated with dental crowding in 3 (17.6%) patients, inter-arches asymmetry in 3 (17.6%) patients or both in 3 (17.6%) patients.

We found statistically significant differences between: the values of Cobb angle of the major spinal curvature and head deviation (p=0.013), malocclusions (p=0.004), Angle classes (p=0.007) and of anomaly types (p=0.025); between the convexity of the major spinal curvature and the facial asymmetry types (p=0.041); between the scoliosis treatment types of and the facial asymmetry types (p=0.037), malocclusions (p=0.001), Angle classes (p=0.011) and anomaly types (p=0.008). We did not find statistically significant results between the other variables studied: scoliosis localization, right/left facial asymmetry, and head inclination to posture the right/left (p>0.050) (tab. I, II, III).

DISCUSSION

In our study we evaluated clinically and photo statically a group of Romanian patients diagnosed with idiopathic scoliosis to establish the relationships between the features of scoliosis (location, convexity of the major curve, Cobb angle and treatment) and the features of facial asymmetry (right/left, overall/lower face, head deviation) and the presence/absence of malocclusions (Angle class, crowding and/or sagittal, transverse or vertical inter-archers asymmetry), presenting some new aspects regarding the inclusion and analysis of these statistical variables.

Most of the study patients were women (94.1%) diagnosed with idiopathic scoliosis at puberty, as it was the case with other studies (12). Patients were assessed orthodontically by clinical and photostatic examinations as they were admitted and treated for their orthopedic condition. Kim *et al.* (4) were conducted their study on frontal and lateral cephalograms, because patients with scoliosis presented to orthodontic clinic. In our study, all our patients had facial asymmetry (right/left and overall/lower face), as other studies have reported (12, 13). Also, all our patients showed right/left and mild/moderate head inclination. In scoliosis, the head changes its inclination in relation to the spine, so that it can compensate for the spine deviation and maintain the orthostatic position. Scoliotic curves in frontal plane and lateral head inclination in posture contribute to the development of various dentofacial asymmetries (14). Body posture and cervical muscles are closely associated with the function of the head and mandible support system (15).

In the patients studied, not all of them had malocclusions. Most common were Angle Class I and III malocclusions (23.5%), dental crowding and occlusal asymmetries (sagittal molar and cuspid, mandibular lateral deviation, unilateral crossbite, canted occlusal plane, and infraocclusions). From our observations, these malocclusions were present only in the orthopedically treated patients (58.8%) and not in the surgically treated ones. In the literature, there are not recent study about the relationship between scoliosis and facial asymmetry, and our data cannot be compared.

Regarding head deviation, presence/ absence of malocclusions, Angle classes and types of anomalies differed depending on the severity of scoliosis. Also, the types of facial asymmetry correlated with the direction of convexity of the major spinal curve. Differences were also found in the types of facial asymmetries, presence/absence of malocclusions, Angle classes and types of anomalies depending on the treatment of scoliosis. All these correlations are original results that are not found in previous literature studies.

The spinal column provides the main support for all segments of human body (head, mandible, shoulders, trunk, hips, legs and feet). When the spinal column is misaligned, whole-body posture is influenced, and all body segments become misaligned as they are taking up unequal muscle loads (16). After surgical correction of spinal deviation, the adaptation of subjacent muscles is slow, with the persistence of functional asymmetries through neuromuscular mechanisms, thus explaining the presence of facial asymmetry and head inclination in posture even after the treatment of scoliosis.

This research may improve the study of young patients with idiopathic scoliosis, because unlike previous studies it identified a relationship with facial asymmetry and the presence/absence of malocclusions. Similar future studies may also find other ways to investigate these patients, so that our data to be comparable.

CONCLUSIONS

In our study, all orthopedic patients presented facial asymmetry (right/left and overall/lower face) and lateral head deviation in posture (right/left and mild/moderate) and only those who received orthopedic treatments (kineto-physiotherapy, braces) presented malocclusions (more commonly Angle Class I and III, dental crowding and interarches asymmetry). The value of Cobb angle correlated statistically with head deviation in posture, presence/absence of malocclusions, Angle diagnostic classes and types of anomalies; the direction of convexity of the major spinal curve was statistically correlated with the types of facial asymmetry; the orthopedic/surgical treatment of scoliosis correlated statistically with the types of facial asymmetry, presence/absence of malocclusions, Angle classes and types of anomaly. These aspects suggest that the interdisciplinary concepts of young people diagnosed with idiopathic scoliosis should be extended, both for the complete and complex skeletal treatment, as well as for the neuromuscular rehabilitation body segment posture.

MODERN ANCHORAGE DEVICES IN ORTHODONTIC THERAPY (Abstract): TADS were one of the most discussed topics of the last decade. It started in the 90' and experienced in the last 15 years an extreme development. The review analyzes the use of mini-implants and mini-plates as orthodontic anchorage, to understand the factors that seem to affect the success rate. The main topics addressed the mini-screw and mini plates studies are as follows: success, failure stability and survival, damage caused and root proximity, dental movements, optical microscopy, torque and strength, placement and location of the mini-screw. **Keywords:** ORTHODONTICS, MINI SCREWS, MINI PLATES.

Anchoring is a determining factor in the success of orthodontic treatment. It allows the application of forces, using a fixed point (anchoring), inducing the displacement of dental units to a given location (1, 2). Designed for orthodontics, bone anchors allow a more conservative treatment, avoid orthodontic surgery and patient cooperation is no longer necessary. They provide an interesting option to bypass conventional anchors such as intermaxillary elastics and extra-oral appliances (3). Considering the treatment plan and the choice of anchor solutions, the orthodontist needs to evaluate pain prevention, restoration of the oral functions, maintenance of the patient's physiognomy, hygiene and responsibility (4).

Prevalence of use

The search was done from the database, Science Direct, by using following key words in French and English according to the current nomenclature: Mini-screws, Mini-vis, Mini-implants, Micro-implants, Mini plates, Skeletal Anchorage System. The selection criteria and filters were as follows: the year of publication 2010 to 2016, from the countries: France, United States, Germany, Taiwan, and Japan, published in French or English; *in vivo* studies, longitudinal, transversal and cohort studies, no isolated clinical cases. The research on *"Science Direct"* revealed 418 articles, only 44 articles were chosen, according to the searched items, of which on mini-screws (36 articles) and the other on mini-plates (8 articles) which includes the following criteria: Title of the author, Year reference, Sample size, Duration of follow-up if mentioned, Themes treated, Conclusion findings.

77% of the articles were on the topic of mini-screws, and 23% on mini-plates.

The main topics addressed in the mini-screw studies were success, failure stability and survival: 47%; Damage caused and root proximity: 13%; Dental movements:13%; Studies under optical microscopy: 7%; Torque and strength: 7%; Placement and location of the mini-screw: 7% (fig. 1).

The topics for the mini-plates took in consideration were survival, success and stability, 34% of studies; Maxillary traction: 22%; Resistance: 11%; Pain: 11%; Recidivism: 11%; Bone stress: 11% of studies on mini-plates (fig. 2).

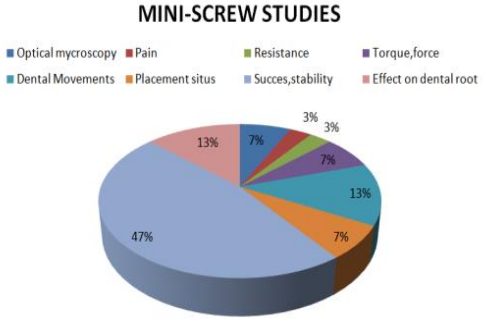

Fig. 1.The main topics for the mini-screw studies

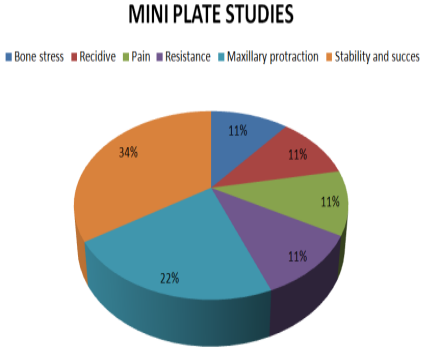

Fig. 2. The main topics for the mini-plates studies

Factors that influence mini-implant therapeutical success

The success of the orthodontic treatment is dependent by three factors: a correct therapeutical plan, parental consent and support and patient cooperation (5).

With regard to success, failures, stability and survival of the mini-screws, the studies showed a very high success rate, for 3162 mini-screws studied on 1548 patients, success was 94.3% (tab. I). Age and sex do not influence the success rate, which remains very satisfactory and similar: 91.2% for men, 92% for women, 86.5% for under 20 years and 89.5% for over 20 years old (tab. II). The success rate of maxillary mini-screws was significantly higher than for the mandible, so we found a success rate of 90% for the maxillary and 79.5% for the mandible (tab. III). The dimensions of the mini-screws are also a factor to consider because the success rate varies in function of the diameter and length chosen. Thus, to obtain a satisfactory success rate, the authors recommend a length of at least 7 mm and a diameter of at least 1.3 mm.

Regarding the pre-drilling or not option, Iwai *et al.* (6) achieved 91.5% success without pre-drilling, and 94.4% with pre-drilling, the main instability and failure is due to contact with the root. Son *et al.* (7) achieved 96% success for both techniques. However, care should be taken with root contact for mini-screws without pre-drilling which has decreased stability. Mini-screws therefore offer a secure alternative with a satisfactory success rate. Regarding damage and root proximity: Shinohara *et al.* (8) showed that root proximity increased the risk of failure of a mini-implant and could affect its stability. In addition, the root can be damaged during a

bad evaluation and placement of the wrong Mini-screw. Ahmed *et al.* (2) found that 41.7% of patients had moderate cement repair, 50% of patients a good repair and 8.3% of patients an excellent repair. No root resorption was observed, nor ankylosis. Nevertheless, other research done by Renjen *et al.* (9) indicates that ankylosis was observed only when the wound root canal was accompanied by a displacement. In addition, according to Lee *et al.* (10) state that prolonged contact of the mini-screw with the root may cause root resorption.

Concerning the dental movements: Heravi *et al.* (11) have studied the effects of intrusion of a molar into supra eruption. The intrusion of the molar was made using 2 mini-screws, one in mesio-buccal and one in mesio-palatine, with a spring in TMA (titanium alloy and molybdenum) which was ligated from the mini- screw to the molar bracket maxillary molars were successfully intruded. Root resorption was observed, 0.3 mm palatal, 0.4 mm mesio-buccal and distovestibular, a slight de-

crease in the peak was observed. The intrusion was 1.5 to 4.5 mm. The use of mini-screws thus makes it possible to avoid, with respect to conventional techniques, the extrusion of adjacent teeth. Senisik *et al.* (12) compared the intrusion of maxillary incisors to reduce a deep-bite in Class II-2 malocclusion, Park and Kwon (13) studied the distalization of posterior teeth in patients using mini-screws. The results were satisfactory they obtained less tilting and rotation of the distal molars. Success was reported by Cernei *et al.* (14) in a case with second molar up righting and space closing after first molar extraction. Thus, we can deduce that the Mini-screws offer an alternative to traditional treatments and avoid stray movements and loss of anchorage.

Studies under ***optical microscopy*** revealed several anomalies: Sebbar *et al.* (15) studied the surface condition of mini-screws after 30 months of use. It has been observed "corrosions in the form of punctures or crevices". Indeed, the corrosion can change the properties of the Mini-screw and mainly its resistance. Corrosion can also release substances inducing and promoting inflammations and other local and general reactions. Sebbar *et al.* (15) also histologically studied peri-implant soft tissues after Mini-screw implantation. In this study there was an inflammatory infiltrate in the tissues, independent of the location of Mini-screw or periodontal disease. Other studies, Petcu *et al.* (16) have shown the correlation between the general status of the patient, implant site and micro-structural details in the biomechanical properties, emphasizing that diabetes can decrease the integration of implant and such the biomechanical proprieties.

Torques and forces: Suzuki *et al.* (17) compared and measured the insertion and withdrawal torque of Mini-screws with and without pre-drilling. The insertion torque of the Mini-screws without pre-drilling was logically greater 14.5 Ncm than when placing the Mini-screws with pre-drilling 9.2 Ncm. This contrast with the value of the torque when removing Mini-screws, in fact the opposite was found with 22 Ncm for mini-screws with pre-drilling and 16.6 Ncm on average for Mini-screws without predrilling. This assumes greater osseointegration for mini-screws placed with pre-drilling, which is an undesired effect because the Mini-screws are not supposed to stay in the mouth and must be easily removed. Suzuki *et al.* (18) studied the ideal insertion torque of Mini-screws with a diameter of 1.3 mm and lengths of 5, 6 and 7 mm. It has been deduced that the ideal torque should be between 5 and 10 N to avoid the failure rate, however this value may differ depending on the type of Mini-screw used and the location used. Motoyoshi *et al.* (19) investigated whether damping and placement torque could provide indications of root proximity to the Mini-screw. In this study 18% of Mini-Screws were in contact with the root. It was found that the placement torque of the Mini-Screws (8.9 Ncm) that were in contact with the root was greater than the Mini-Screws without contact with the root of about (7.5 Ncm). Nevertheless, further studies on this subject are needed to prove this relationship and confirm this study.

Regarding placement and location of Mini-screws: Kau *et al.* (20) showed that 3D imaging is necessary for optimal placement of Mini-screws, indeed in this study imaging showed that 65.2% of placed Mini-Screws were in contact with

the periodontal ligament. Park, Hwang Bo and Kwon (13) have shown in their study that it is preferable to place the mini-screws distal to the point of contact from 0.5 to 2.7 mm with an inclination of 10 to 20° distally.

Factors that influence mini-plate therapeutical success

Discusses studies on mini-plates regarding the survival, success and stability: studies have shown a very high success rate, it is 96% in our case which is a higher success rate than for Mini-screws (tab. IV). Lee *et al.* (10) has shown that several factors can influence the success of Mini-Plates, the first important factor is hygiene, and then comes the second factor which is the experience of the operator who proceeds to surgery. Hygiene is however an important factor for patients who receive dental treatments, more than half of the subjects in a study made by Barlean *et al.* (21) considering appropriate to involve in infection control in the dental office.

TABLE IV

Studies regarding the survival, success and stability on mini-plates

	TOTAL	476	286		96%

Concerning studies on maxillary protraction: Cagla Sar (22) studied the efficacy of maxillary pro- traction with and without bone anchorage in the case of Class III with maxillary developmental deficit; 2 mini plates were placed at the maxillary level in the lateral of the piriform orifice, and a facial mask was placed at its level. The treatment was 6.78 months on average for the group with mini-plates, and 9.45 months on average for the group with a conventional treatment. The maxillary advanced 2.3mm for the group with mini-plate against 1.83 mm for the group with conventional treatment. The protraction rate was 0.48 mm per month for the group with mini-plates against 0.24 mm per month for the group with conventional treatment. The posterior rotation of the mandible increased the facial height in both groups, but this was much more marked in the group with conventional treatment. Protrusion and mesialization of maxillary teeth found in the healthy group with conventional treatment was eliminated in the group with mini-plates. Elnagar *et al.* (23) compared maxillary protraction in the case of a class 3 with maxillary developmental deficiency using mini-plates according to 2 techniques. The first technique was as previously seen infrazygomatic mini-plates with facial mask. The second technique consists in placing 4 mini-plates, 2 in maxillary infrazygomatic, as well as 2 in the mandibula at the level of the mental symphysis, and the application of elastics at this level. The results obtained according

to the two methods were satisfactory, and class III malocclusion was corrected in both cases. Nevertheless, the method with 4 mini-plates gave better results, because it allowed a better control of the retro inclination and the vertical changes of the mandibular incisors. Pei Chen Lu *et al.* (24) studied the resistance of mini-plates, applying several forces, in different directions; the vertical resistance was 106.8 Ncm and the horizontal resistance 233 Ncm. The mini-plates are thus perfectly suited to the application of orthodontic and orthopedic forces without risk of breakage of the material. Concerning recidivism, Marzouk *et al.* (25) studied the recurrence rate after 4 years following the use of Zygomatic mini-plate for the intrusion of the first molar as well as for the treatment of an open bite. Recurrence for molar intrusion was 10.2% in the first year and 13.4% after 4 years. The recidivism of the open bite was 8.19% in the first year and 11.8% after 4 years. Thus, we can say that 4 years after treatment, the recurrence rate is very low for Zygomatic intravenous mini-plate treatments as well as for open-bite treatments. Regarding bone stress: Yen Wen Huang *et al.* (26) studied bone stress caused by different forms of mini plates using 3D simulation. As a result, the bone stress was greater on the mini-plates in I then in L then in Y and finally in T. The bone stress also decreased when the number of fixing screws was more numerous.

CONCLUSIONS

The mini-screws have a high success rate: they open the possibility to several dental movements such as intrusion, retrusion of the frontal incisors, and other distalisations by avoiding parasitic movements and loss of anchorage. It is advisable to take precautions during placement, to avoid placement in the periodontal ligament or even in extreme cases a root contact. The choice of material to use is also essential in practice because it will determine the operating mode. It is desirable to use mini-screws without pre-drilling due to their low osteointegration, which allows them to be removed easily. Mini-plates have also a very high success rate (96%), this success is influenced mainly by the hygiene of the patient by the experience of the practitioner. To avoid bone stress, it is best to use Y or T mini-plates. The resistance of mini-plates is important and allows the application of orthopedic forces. The maxillary protraction can also be done using 4 mini plates placed on each arch in bilateral with elastics at their levels. Patient cooperation is no longer necessary, and results are better. The recidivism rate is low. Their numerous indications make it possible to replace the conventional anchorage and open the way to new therapies in the future.

SIMILAR EFFECTS OF RADIOSURGERY ON BOTH CYSTIC BRAIN METASTASYS AND SOLID TUMORS

A study regarding 426 patients with brain metastases who undergone radiosurgery treatment at the Tianjin Cancer Hospital and Institute over a 4-year period shows that although considered a treatment mode especially used for solid tumors, radiosurgery is also beneficial metastasis of the cystic brain, where this procedure is less used due to poor prognosis. although the rate of tumor shrinkage is less accelerated, the final results are almost identical (Wang H, Liu X, Jiang X, Song Y, Wang X, Wang J, Dong Y, Li F, Wu Z, Zhang Y, Yuan Z. Cystic brain metastases had slower speed of tumor shrinkage but similar prognosis compared with solid tumors that underwent radiosurgery treatment. *Cancer Manag Res* 2019; 11: 1753-1763).

CLINICO-RADIOLOGIC CORRELATIONS IN CEREBRAL PALSY (Abstract). The aim of this study was to determine clinico-radiologic correlations, using cranial magnetic resonance imaging (IRM)/computed tomographic exam (CT), in cerebral palsy (CP). **Material and method**: We studied 129 children (86 males, 43 females; aged 2-18 years) diagnosed with different types of CP. Computed tomographic examinations was performed in 100 (77,52%) of children and IRM in 29 (22,48%). **Results**: In 19 (14.72%) children the neuroimaging exam was normal. At 110 (85.28%) patients the IRM/CT showed different types of abnormalities. The most common neuroimaging findings was ventriculomegaly (38 cases), followed by focal infarct (28 cases), periventricular leukomalacia (17 cases), cortical and cortical/subcortical atrophy (13 cases), basal ganglia lesions (12 cases) and cortical migration and organization problems (12 cases). The CT/IRM abnormalities was associated in 65.45% of cases with mental retardation and 44,54% presented epileptic seizures. In CP neuroimaging findings are common, but variable and IRM/CT change correlates with neurological assessment. **Conclusion**: Patients with CP and mental retardation or/and epilepsy were more likely to have obvious CT/IRM changes. **Key words:** CEREBRAL PALSY, NEUROIMAGING FINDINGS, CHILD

Paralizia cerebrală (PC) este o afecţiune neprogresivă a mişcării şi posturii, care determină un deficit motor permanent şi reprezintă în multe cazuri prototipul tulburărilor de dezvoltare, fiind cea mai frecventă dizabilitate ,,fizică" a copilăriei care afectează sever dezvoltarea copilului (1). Diagnosticul de PC se bazează pe un istoric de dezvoltare neuromotorie anormală datorată unei leziuni cerebrale neprogresive, pe examene clinice multiple şi explorare neuroimagistică (2).

Examenele neuroimagistice moderne sunt utile atât pentru stabilirea diagnosticului pozitiv, a prognosticului cât şi pentru diagnosticul diferenţial al PC, deoarece consecinţele clinice depind de topografia leziunii (3). De asemenea, explorarea neuroradiologică realizată precoce oferă posibilitatea stabilirii unei legături între tipul agresiunii şi prezenţa leziunilor cerebrale (4). La copiii cu PC cele mai frecvente anomalii neuroimagistice sunt reprezentate de infarcte arteriale focale (22%), malformaţii cerebrale (14%) şi modificări la nivelul substanţei albe periventriculare (12%) (5).

Scopul studiului a fost de a determina la pacienţii de vârstă pediatrică cu PC existenţa unei corelaţii între aspectul clinic şi modificările depistate la examenul neuroradiologic.

MATERIAL ŞI METODĂ

Lotul de studiu a inclus 129 de copii (43 fete şi 86 băieţi) cu vârsta cuprinsă între 2-18 ani, diagnosticaţi cu diferite forme de PC: 114 (89,37%) cu forme spastice, 8 (6,2%) cu PC diskinetică, 5 (3,87%) cu PC

TABELUL I
Aspecte neuroimagistice la pacienţii cu paralizie cerebrală studiaţi

Aspecte neuroimagistice (CT/IRM cerebral)	Nr. pacienţi
Normal	19
Porencefalie	28
Agenezie/hipoplazie de corp calos	2

ataxică şi 2 (0,56%) cu PC mixtă.

La 100 (77,52%) dintre pacienţi s-a efectuat CT-scan cranio-cerebral, 29 (22,48%) au beneficiat de IRM cerebral, iar 87 (67,44%) aveau efectuată din perioada neonatală ecografie transfontanelară.

Leziunile relevate de examenul CT şi/ sau IRM au fost clasificate în 4 grupe: leziuni corticale, leziuni centrale sau periventriculare, tablouri mixte şi anomalii de dezvoltare.

REZULTATE

La 19 (14,72%) copii aspectul neuroimagistic a fost normal, 4 (21,05%) dintre aceştia fiind cu forme severe de PC, iar 15 (78,95%) cu forme uşoare sau medii de paralizie cerebrală.

La 110 (85,28%) pacienţi s-au evidenţiat neuro-radiologic leziuni localizate la diferite nivele (tabelul I). Dintre aceştia 47 (42,73%) aveau forme severe de PC, 24 (21,82%) forme medii şi 39 (35,45%) forme uşoare de PC. De asemenea, 72 (65,45%) dintre bolnavii la care s-au observat modificări la CT/ IRM cerebral aveau întârziere mintală, iar 49 (44,54%) prezentau crize epileptice.

Leziunile porencefalice au fost evidenţiate la 28 (21,70%) pacienţi (fig. 1A, 1B), dintre care 27 erau clinic diagnosticaţi cu hemiplegie spastică şi unul cu tetraplegie spastică.

La 13 (10,07%) copii, toţi având forme spastice sau mixte de PC, s-a observat la examenul neuroimagistic atrofie corticală/ cortico-subcorticală, probabil consecinţa hipoxiei şi ischemiei perinatale (fig. 2A, 2B, 2C). Hemiatrofia cerebrală a fost prezentă în 2 cazuri de hemiplegie spastică.

La un număr de 38 pacienţi s-a remarcat dilatare ventriculară de cauză posthemoragică sau infecţioasă din perioada neonatală, dintre aceştia 11 (28,94%) au prezentat în evoluţie hidrocefalie (fig. 3A, 3B).

Leziunile localizate la nivelul ganglionilor bazali şi a talamusului au fost prezente la 12 copii (9,3%), dintre care 8 (66,66%) erau diagnosticaţi cu PC diskinetică, 3 (25%) cu tetraplegie şi unul (8,34%) cu diplegie spastică.

Calcificările cerebrale au fost secundare infecţiilor intrauterine, în special cu citomegalovirus şi *Toxoplasma gondi*, fiind prezente la examenul neuroimagistic în 9 cazuri.

În cazurile cu PC ataxică modificările neuroimagistice au fost limitate la fosa posterioară la 4 copii; la un pacient anomaliile au fost localizate atât la nivelul cerebelului cât şi a lobilor parietali.

culară (LPV) au fost remarcate la 17 pacienţi (13,17%), toţi diagnosticaţi cu forme spastice de PC: 10 (58,82%) cu diplegie spastică, 4 (23,52%) cu tetraplegie spastică şi 3 (17,66%) cu hemiplegie spastică. Tulburările de migrare şi organizare corticală au fost înregistrate la 9,30% din copiii cu PC luaţi în evidenţă şi au fost reprezentate de displazie corticală (2 cazuri), polimicrogirie (3 cazuri), schizencefalie (4 cazuri), pahigirie/lisencefalie (3 cazuri) (fig. 3C). Displaziile corticale au fost prezente la copiii cu forme spastice de PC.

DISCUŢII

Examenele neuroimagistice sunt importante la copiii cu PC deoarece în majoritatea cazurilor pot explica etiologia deficitului motor sau a unor patologii asociate. Candy (1993) a stabilit cu ajutorul IRM cerebral etiologia la 23% din pacienţii cu PC investigaţi, iar Cohen (1981) a remarcat o corelaţie între modificările prezente la CT cranio-cerebral şi existenţa crizelor epileptice sau a retardului mintal la copiii hemiplegici. Pe de altă parte, Molteni (1987) apreciază că, la pacienţii cu PC, nu există o legătură clară între aspectele morfologice şi cele clinice care s-ar putea explicata prin complexitatea modificărilor structurale şi prin proprietăţile de remodelare a SNC după injurii pre/postnatale. În lotul studiat 65,45% dintre bolnavii la care s-au observat modificări neuroimagistice aveau întârziere mintală, iar 44,54% prezentau crize epileptice.

Ashwal (2004) apreciază eficienţa CT cranio-cerebral în medie de 77% în depistarea anomaliilor cerebrale şi a IRM cerebral de 89%. Aspectul normal al examenului neuroimagistic apare la 11,7-31% dintre copiii cu PC (5, 10). În studiul nostru la 14,72% dintre pacienţi nu s-au identificat anomalii neuroradiologice.

Analizându-se modificările înregistrate la CT/IRM cerebral la ceilalţi copii cu PC urmăriţi s-a încercat realizarea unei corelaţii clinico-radiologice. Astfel, s-a remarcat că toţi pacienţii cu PC diskinetică aveau leziuni localizate la nivelul ganglionilor bazali şi a talamusului. Aceste date sunt în concordanţă cu cele prezentate de Bax (2006) care a observat anomalii în aceste regiuni la 75,6% dintre copiii cu forme extrapiramidale de PC.

De asemenea, în lotul studiat toţi copiii cu PC ataxică au prezentat anomaliile neuroimagistice care în 4 cazuri au fost limitate la fosa posterioară, iar într-un caz modificările au fost localizate atât la nivelul cerebelului cât şi a lobilor parietali. Aceste observaţii se regăsesc şi în studiul lui Miller (1989) care utilizând CT cranio-cerebral la 29 de bolnavi cu PC ataxică, a evidenţiat anomalii de fosă posterioară la 28% din pacienţi, leziuni şi la nivelul lobilor parietali la 55% şi aspect normal la 38% dintre cazuri.

La pacienţii cu PC spastică se observă frecvent leziuni cortico-subcorticale, malformaţii cerebrale şi anomalii ale substanţei albe. Leziunile corticale focale au fost prezente în special la copiii hemiplegici, date asemănătoare cu cele raportate şi de alţi autori. Wu (2006) a observat anomalii focale la 45% din pacienţii cu hemiplegie spastică investigaţi. De asemenea, autorul remarcă frecvenţa crescută a displaziilor corticale (14%). La rândul său, Bax (2006) a observat la IRM cerebral malformaţii la 9,1% din pacienţii de vârstă pediatrică urmăriţi şi anomalii ale substanţei albe la 71,3% dintre cei cu diplegie spastică, la 34,1% cu hemiplegie şi la 35,1% cu tetraplegie. În studiul nostru, tulburările de migrare şi organizare corticală au fost prezente la 12 (9,30%) copii cu PC spastică, iar leziunile de LPV au fost observate la 17 pacienţi, dintre care 58,82% erau diagnosticaţi cu diplegie spastică, 23,52% cu tetraplegie şi 17,66% cu hemiplegie.

CONCLUZII

Explorarea neuroimagistică este utilă la copiii cu PC deoarece informaţiile furnizate sunt importante în înţelegerea etiologiei şi aspectelor clinice. Pacienţii cu PC care prezintă anomalii neuroimagistice au un risc crescut pentru crize epileptice şi întârziere mintală. Evaluarea morfologiei cerebrale prin examen neuroradiologic trebuie inclusă în protocolul de evaluare a fiecărui copil cu paralizie cerebrală.

NOUTĂŢI

DISECŢIA DE AORTĂ ŞI ABUZUL DE AMFETAMINE

Incidenţa disecţiei de aortă (DA) este estimată la aproximativ 2,9 cazuri pentru 100000 de adulţi vârstnici, fiind rară la adulţii tineri (doar 7% dintre subiecţii cu DA având vârsta sub 40 de ani). Un studiu recent pune în discuţie o posibilă legătură între consumul de anfetamine şi riscul de DA la adulţii tineri : printre subiecţii cu vârsta cuprinsă între 18 şi 40 de ani spitalizaţi pentru diverse maladii între anii 1995-2007 au fost identificate 3116 de DA toracice sau toraco-abdominale. După ajustările efectuate asupra factorilor de risc cunoscuţi (vârstă, HTA, consum de cocaină, tabagism, dislipidemie, boli cardiovasculare ereditare, vascularite inflamatorii, traumatisme, sindrom Turner), consumul şi/sau dependenţa de amfetamine s-a dovedit statistic legate de un risc major pentru DA (odds ratio : 3,33 ; interval de încredere la 95% : 2,37-4,69 ; $p < 0,0001$). Stupefiant ! (Westover J et al. Aortic dissection in young adults who abuse amphetamines. *Am Heart J* 2010, 160 : 315-321).

MORPHOLOGICAL DIAGNOSIS OF MYOCARDIAL INFARCTION-IN THE LIGHT OF THE CURRENT CLINICAL CLASSIFICATION (Abstract): Ischemic heart disease is one of the leading causes of morbidity and mortality worldwide. Diagnosis of myocardial infarction (MI) can be a challenge, especially in the absence of acute coronary occlusion. Accurate histopathological identification and timing of myocardial infarction in humans are of particular importance, especially for clinical practice or for legal medicine. The post-mortem diagnosis requires not only up-to-date knowledge of coronary and myocardial ischemic pathology, but also a correct interpretation of these features in relation to the clinical scenario of the disease. For these reasons, it is important for pathologists to know the different clinical types of MI and to differentiate myocardial infarction from other forms of myocardial injury. **Keywords**: ISCHEMIA, MYOCARDIAL INFARCTION, SMALL VESSEL DISEASE.

Acute ischemic cardiac syndromes, which are acute myocardial infarction (MI), unstable angina and sudden coronary death, are acute life-threating diseases with high mortality rates (1). Coronary artery disease (CAD), which is the basis of most cases of MI, and also the ischemic myocardial pathology in various stages of injury and repair, is extensively studied to improve post-mortem diagnosis (2). Auxiliary techniques for highlighting ischemic injury have been developed or are now under investigation for improving diagnosis (3). Recent acquisitions, such as non- or minimally invasive post-mortem imaging techniques used to detect coronary occlusion and ischemic injuries, nowadays they attract much interest, as autopsy rates tend to decrease in many countries (4, 5). However, in some cases, these diagnostic modalities alone may prove inadequate or insufficient to explain a clinical suspicion of myocardial ischemia. Examples are sudden coronary death without thrombi, cases of peri-procedural myocardial ischemia after therapeutic coronary interventions or non-coronary causes of ischemia (6). Last but not least, there are certain types of myocardial injury, other than ischemic, that need to be considered. This is reflected in the current clinical classification of myocardial infarction, which differentiates various types of pathological mechanisms and evolving treatment strategies (7). Our paper proposed to review the previous MI appearances and to highlight the new concept

in the light of the current clinical MI classification.

1. Definition. The 4th universal definition of myocardial infarction (2018), agreed by the members of the European Society of Cardiology, American Heart Association and World Heart Association Federation, etc., describes five distinct MI subtypes based on large variety in the pathophysiology aspects of MI encountered in clinical practice. The term acute myocardial injury should be used when there is evidence of increased cardiac troponin (cTn) values, what many doctors label as "troponin leakage", "troponinemia" (8).

The known clinical diagnosis of MI is based on the presence of increased levels of cardiac troponin, in combination with prolonged chest pain, ECG records or regional wall anomalies indicative of recent onset ischemia or angiographic detection of a coronary thrombus, while the new concept proposes the need for differentiation of myocardial infarction from myocardial injury by highlighting the peri-procedural myocardial injury after cardiac and non-cardiac procedures and to use of cardiovascular magnetic resonance and computerized coronary tomographic angiography in diagnosis of suspected myocardial infarction (4, 5).

2. The new MI classification. In 2018, a group of pathologist experts differentiate five distinct MI subtypes (Table I) according with various pathophysiology MI appearances (9).

TABLE I

The new Myocardial Infarction classification

MI Types	ESC/AHA/ACC/WHF classification of MI 2018
Type 1	Acute atherothrombotic occlusion or mural thrombus with critical flow reduction initiated by plaque rupture or erosion
Type 2	Ischemic injury due to a myocardial oxygen supply-demand mismatch, which is not caused by coronary atherothrombosis (tab. II)
Type 3	Cardiac death in a clinical setting suggestive of ischemic injury (chest pain, ECG changes) but without definitive cardiac biomarker evidence
Type 4	PCI-related ischemic injury < 48 hrs. after procedure. Includes also cases of MI due to late stent thrombosis or restenosis
Type 5	CABG-related ischemic injury < 48 hrs. after the procedure

Type I of MI is the result of acute coronary atherothrombosis. In clinical studies, coronary thrombotic events can be observed in approximately 80% of patients with acute coronary syndromes (ACS). They are still classified based on ECG findings as either ST elevation types of MI (STEMI) or non-ST elevation types of MI (non-STEMI).

The most common cause of acute myocardial ischemia is atherothrombotic occlusion of a coronary artery (10). This implies that, in cases of sudden death, acute coronary occlusion may explain the arrhythmic death. The underlying pathology of mural or occlusive coronary thrombosis may be due to rupture or erosion of the plaque, or less frequently, to protruding calcified nodules. Also, intraplaque bleeding contributes to the acute flow reduction in these

cases (11).

Irreversible damage of myocardial cells is the hallmark of MI also known as ischemic necrosis, which is histologically a "coagulative" type necrosis. It should be differentiated from other types of necrosis, which can be found at autopsy, the type of contraction band necrosis, which is a feature of many other forms of myocardial injury (12).

The onset of ischemic necrosis is not immediate. The acute ischemic lesion develops in the "area at risk" (area of perfusion of the obstructed artery). Ischemic necrosis of myocardial cells can be detected with the current diagnostic methods after about 2-4 hours, but the onset depends on many variables, such as collateral circulation and microvascular pathology. After the onset of occlusion, myocardial necrosis evolves in a wave front-like pattern over several hours from the endocardium to the epicardium in the "risk area", eventually causing a transmural MI. During the wave evolution of the myocardial necrosis, ventricular arrhythmias may occur in the sub endocardium, even in the earliest stage of still reversible damaged myocardium, but also several hours after occlusion, when the wave of necrosis has evolved substantially. This is also important for pathologist to realize that early onset arrhythmia and SCD is an early sign of myocardial injury in the absence of any other changes, prior to the development of myocardial necrosis wave. It should be noted that later stages of myocardial necrosis, including fibrous scars may serve as a substrate for life-threatening arrhythmias (13).

Topographic distribution of MI in the heart. According to the involved myocardial region, MI is classified as regional when it involves the area of perfusion of one epicardial artery or circumferential when it affects a large part of the circumference of the ventricular wall. Regional MI can be either transmural, usually associated with ST segment elevations on ECG (STEMI), or only subendocardial (non-STEMI). Circumferential MI is mostly due to the general decrease in coronary perfusion pressure that interests the three major coronary artery branches and is localized in the subendocardial region only (fig. 1).

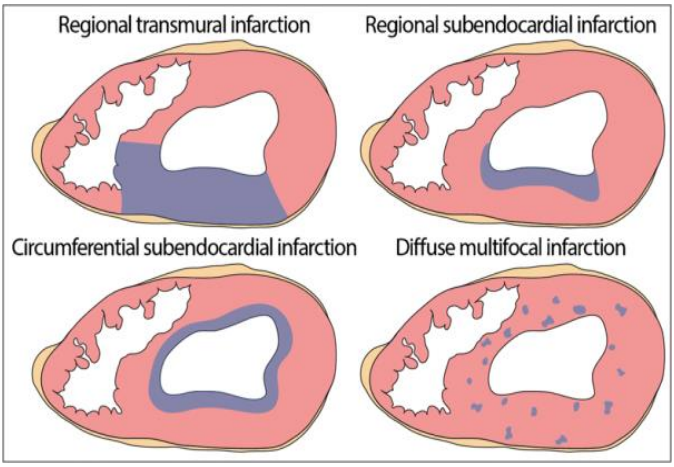

Fig. 1. Topographic distribution of MI in the heart.

The location of the MI is related by the perfusion territory of the three large epicardial arteries, such as: (a) obstruction of the anterior descending left coronary artery determines an antero septal AMI located in the anterior wall of the LV, 2/3 anterior IVS and the apex of the heart (40%; (b) obstruction of the posterior descending coronary artery causes a postero-inferior AMI, located in the posterior or inferior wall of the LV and 1/3 posterior of the IVS (30%); (c) obstruction of the circumflex branch of the left coronary artery gives a lateral AMI, located in the lateral wall of the LV, except the heart apex (20%); (d) obstruction of the left coronary artery before artery branching causes a massive antero-lateral AMI (10%) (14).

Other MI locations. Atrial infarctions occur in relation with ventricular infarctions and have a variable incidence in patients with MI ranging from 0.7 to 42%. Isolated atrial infarctions are rare (15). The main cause of atrial MI is coronary atherosclerosis. The pathological significance is related by the two potential complications of atrial MI: the first is the mural thrombus formation followed by thromboembolization, especially in patients with atrial fibrillation (16); the second is the rare atrial rupture that can result in cardiac tamponade (15).

Postmortem diagnosis of MI is based on gross and histological changes. Clinical-pathological correlations can be made by differentiating four evolutive stages of the lesions, which are related to the important clinical scenarios of ischemic morbidity and mortality (9).

a. **The earliest stage of cell death (the first hours).** Under experimental conditions, transmission electron microscopy (TEM) reveals ischemic changes (mitochondrial swelling and cardiomyocyte interruptions already occurring 10 minutes after onset). This method is not useful for detecting early human ischemia due to similarities between early ischemic changes and autolysis. The earliest light microscopic changes are regional wavy pattern of myocytes as a result of stretching of dead non-contractile myocytes due to adjacent functional myocardium during the cardiac cycle (8). In the first hours, the interstitial edema appears, and early onset of coagulative necrosis shown by cytoplasmic hypereosinophilia also develops, representing the early onset of coagulative necrosis (fig. 2). Enzymatic detection of early necrosis in fresh myocardium is made by using NBT reaction which is reported to be positive from 3 hours after the onset of ischemia. NBT stains only in the presence of intracellular lactate dehydrogenase (LDH). Nitro blue tetrazolium (NBT) staining of a fresh myocardial slice demonstrates early ischemic necrosis (due to leakage of enzymes from irreversibly damaged myocardium) while the vital myocardium is stained in deep purple (9, 14).

b. **Inflammatory stage (first week).** Neutrophil infiltration begins at MI border. Neutrophils can also invade the central area of a small MI, but this occurs much later depending on the size of the infarction. Coagulation necrosis continues by revealing the nuclear changes and myocyte disintegration. This is associated with heavy interstitial infiltrates of intact neutrophils and karyorrhexis of the neutrophils. Early phagocytosis of dead cells by macrophages, infiltration of other mononuclear cells, such as lymphocytes, and the onset of marginal fibrovascular response, show a further continuation of the healing process (fig. 3).

However, in large MIs, residual necrotic areas can still be detected even after many

weeks. Macroscopically, MI acquires a gray-yellowish color. At this stage, the necrotic myocardium is weak and vulnerable to septal, papillary muscles or free wall ruptures in case of transmural infarction, all with high mortality (9, 14).

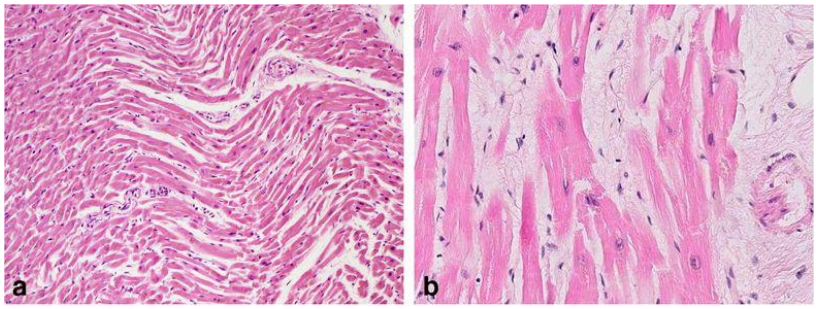

Fig. 2. a- myofiber waviness; b-interstitial edema.

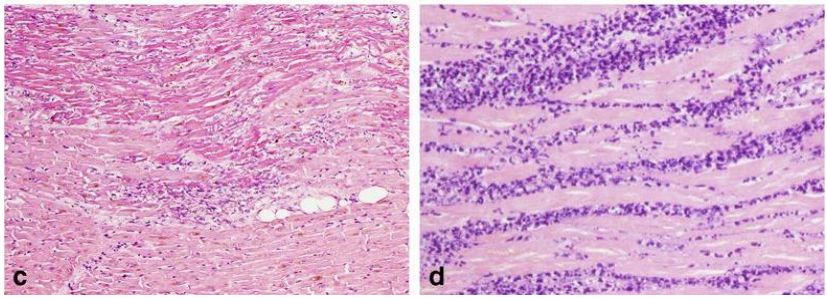

Fig. 3. c-hyper eosinophilia and coagulative necrosis of cardiomyocytes; d- heavy granulocyte infiltration.

c. **Granulation tissue stage (one week to several weeks).** This stage is characterized by capillary and fibroblasts proliferation with initial deposition of loose arranged collagen fibers and a persistent inflammatory infiltrate of lymphocytes, rare plasma cells, macrophages including siderophages, while the number of neutrophils decreases. Granulation tissue is most abundant at 2-3 weeks (fig. 4). Grossly, this tissue can be seen as a gelatinous hyperemic border around the necrosis (9, 14).

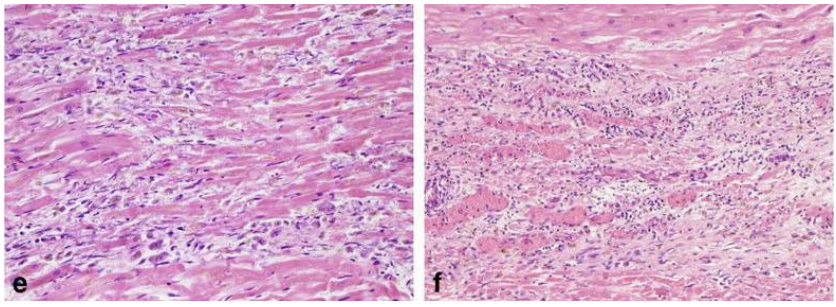

Fig. 4. e-macrophages infiltration; f - granulation tissue with formation of micro vessels.

d. **Late fibrotic stage (scarring) (over several weeks).** The granulation tissue gradually disappears and is replaced by dense collagen leading to fibrotic scars, which usually contain dilated vessels with thin walls (fig. 5). The rate of granulation tissue disappearance depends on the size of MI but is completed by the second month in most cases, leaving a hypocellular scar (9, 14).

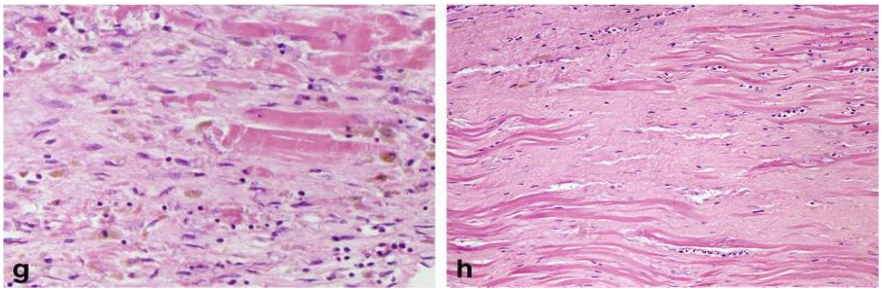

Fig. 5. g-fibroblast proliferation; h-dense fibrous scar replacing myocyte loss.

Type 2 MIs are heart attacks that result from an imbalance between myocardial oxygen demand and oxygen supply and are not due to acute disruption of coronary plaque and thrombosis (tab. II). In general, the frequencies reported by type 2 MI ranges from 10 to 30% of all patients with MI (17).

For example, MI with normal or low-grade angiographic stenosis (stenosis ≤50%) is a clinically recognized syndrome (called MI with non-obstructive coronary arteries, MINOCA), caused by a variety of pathology in and outside the heart. In a case of a fixed stenotic stable plaque of > 75% stenosis, exercise or spasm, can cause irreversible myocardial injury (18). Stenosis of 90% or more causes myocardial ischemia, even at rest, can be observed as a point-like/pinpoint lumen, less than 1 mm in diameter. Many of these stenoses are caused by fibro-calcified plaques but without thrombus. In these cases, microscopy of the malperfused territories of the myocardium can be a helpful adjunct in diagnosis.

TABLE II.

Causes of Myocardial Infarction of 2nd type

	Causes of MI without atherothrombotic coronary artery disease
Fixed coronary atherosclerotic plaques	In combination with non-coronary causes of oxygen demand-supply imbalance
Non-atherosclerotic coronary artery disease	Spasm/SVD, vasculitis, dissection, embolism, congenital anomalies, fibromuscular dysplasia, iatrogenic (stent or graft restenosis), PCI-related no-reflow
Non-coronary cardiac oxygen demand-supply imbalance	Sustained tachyarrhythmias, bradyarrhythmia, LV hypertrophy and/or dilatation
Extra cardiac oxygen demand-supply imbalance	Respiratory failure, severe anemia, hypovolemic shock

Morphologically, there are no distinctive gross or histologic hallmarks of coronary artery spasm (CAS). Drugs (androgenic anabolic steroids), physical and mental

stress are considered as precipitating factors of spasm (18). The presence of an area of regional myocardial infarction could indicate spasm in the artery when no other explanation for infarction is provided. It can affect either the normal or atherosclerotic epicardial arteries or the microcirculation, or both. It is the result of vascular smooth muscle cell hyper-reactivity as a pathophysiological substrate for spasm.

Microvascular dysfunction (MVD) is a functional impairment of flow in intramyocardial vessels and may cause MI. It is especially seen in hypertrophic and dilated hearts, preferentially in the subendocardial areas of the myocardium. Moreover, microvascular embolization can occur in patients with atrial fibrillation (19).

Type 3 MI. The patients presenting with type 3 MI have new ECG changes or are in ventricular fibrillation (VF), but who die before cardiac biomarkers of ischemia can be identified. A frequency of 3-4% of total MI has been reported. HP study of the myocardium reveals coagulative myocytolysis as a hallmark for VF (20).

Type 4 MI is diagnosed by a significant increase in cardiac biomarkers related to percutaneous coronary revascularization procedure. It can be temporally linked to the procedure (within 48 hours) leading to critical reduction of myocardial blood flow; it may be also due to acute complications of a device, such as in-stent thrombosis, coronary dissection or the late stent complications, such as restenosis and late-onset thrombosis (21).

Prompt restoration of coronary blood flow preserves the myocardium. Histological changes include hemorrhage, contraction band necrosis, endothelial swelling, and vascular plugs.

Type 5 MI is due to ischemic injury associated with coronary artery bypass grafting (CABG) that occurs within 48 hours of the procedure. It can be related to the procedure or to low-flow or reperfusion injury (9).

3. Ischemia and reperfusion and other forms of injury. After coronary intervention, PCI or CABG, the myocardial and microvascular pathology is characterized by peri-procedural ischemia, myocardial reperfusion injury and no-reflow phenomena, in association with pre-existent ischemic pathology of the myocardial risk area at (22).

Contraction band necrosis (CBN) of myocytes is the earliest sign of myocardial injury, arising at 10 min after onset of ischemia and reperfusion, and is characterized by the occurrence of thick eosinophilic bands in the cytoplasm of cardiomyocytes due to clustering of hypercontracted contractile proteins (fig. 6). After flow restoration (reperfusion), dying cardiomyocytes with ischemic damaged cell membranes are exposed to high serum Ca^{2+}concentrations, leading to massive Ca^{2+} influx followed by irreversible hypercontraction (CBN). CBN occur frequently in the periphery (the 'border zones') of ischemic infarctions, which is due to microvascular collateral perfusion from adjacent vital myocardium (23).

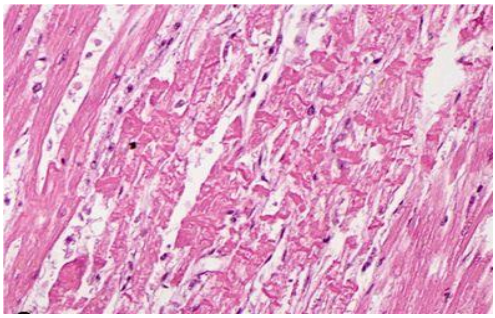

Fig. 6. Contraction band necrosis

Contraction bands are not only a feature

of ischemic infarction alone. They can also be observed after CPR including defibrillation and other trauma. CNB are related to PCI, but they also are observed in situations of catecholamine excess, free radical injuries, etc. CBN is accompanied by microvascular injury leading to endothelial swelling, microvascular obstruction and interstitial hemorrhages (9, 24).

4. Experts appreciation. The 2018 New Concepts in differentiation of myocardial infarction from myocardial injury consists (7) in: (a) Highlighting peri-procedural myocardial injury after cardiac and noncardiac procedures; (b) Use of cardiovascular magnetic resonance in suspected myocardial infarction; (c) Use of computed tomographic coronary angiography to define the etiology of myocardial injury.

In both cases of MI associated with PCI or CABG (clinical types MI 4 and 5), the application of post-mortem coronary angiography should be considered. This method allows to localize stents, to visualize the patency of stents and grafts and to evaluate the distal arterial bed and presence of collateral vascularization. Histological sampling of the involved myocardium is crucial for investigating the presence of myocardial injury.

CONCLUSIONS

Histopathological exam represents the first and last opportunity to make an accurate diagnosis in AMI and SCD. The methods of investigation has been updated including not only a protocol for examination of the heart and histological sampling, but, when necessary, toxicology, microbiology, biochemistry, genetic, molecular investigation and imagistic methods.

PRELIMINARY STUDIES ON THE INFLUENCE OF PEPTIDE POPULATIONS ON THE SURFACTANT PROPERTIES OF A HYDROLYZATE (Abstract): **Aim:** To highlight the involvement of the peptide population in the variation of surface tension of a hydrolysate obtained from bovine hemoglobin. **Material and methods:** Hydrolysis was performed using a 1% (w/v) hemoglobin solution. The hydrolysis reaction was ended after 2.5 minutes, 10 and 120 hours using a 5M NaOH solution to adjust the pH value to 9.5 in order to inactivate pepsin. The HPLC system used included a Waters TM 600 pump controller and a Waters 996 diode bar detector. The surface tension was measured using a KRUSS DSA 10Mk2 tensiometer. **Results:** The analysis of the chromatographic profiles obtained for the peptic hydrolysates revealed the existence of many bioactive peptides. Large peptides were present in the 2.5-minute hydrolysate and hem could be detected (38 minute-retention time). For the 10- and 120- hour hydrolysates, hem could be detected with a retention time of 35 minutes. Surface tension varied at lower concentration, while at higher concentrations it was almost constant. The 1% (w/v) unhydrolyzed hemoglobin solution had a 40 $mN \cdot m^{-1}$ surface tension. **Conclusions:** The process of hydrolysis influenced the surface tension of protein hydrolysate solutions. It was found that the hydrolysates exhibited reduced surface tension when compared with unhydrolyzed hemoglobin. A preliminary characterization of hydrolyzers proved they had similar stability. **Keywords:** PEPTIDIC POPULATION, SURFACE TENSION, BOVINE HEMOGLOBIN.

The nutritional properties of food proteins have been investigated for many years, and it was found to depend on their amino acid content (1, 2). The possibility of releasing the biologically active peptides from food proteins has gained a lot of interest recently due to their effects on numerous physiological functions. Bioactive peptides are short sequences of amino acids, that are inactive within the sequence of the parent protein, but once released, they have positive effects on various body systems including the circulatory, gastrointestinal, and nervous sys-

tem. Such peptides can be released through chemical or enzymatic hydrolysis (3, 4).

Enzymatic protein hydrolysis is a reaction that involves the breakdown of peptide bonds under the action of an enzyme, resulting in the release of longer or shorter fragments, called peptides. The use of enzymatic hydrolysis to produce bioactive peptides is preferred to microbial fermentation due to the short reaction time and predictability (4, 5). As a result of enzyme hydrolysis, an improvement of organoleptic properties of proteins is observed and very complex peptide populations are obtained. However, numerous tests performed on these hydrolysates reveal low concentrations of several peptides of multiple interests, the so-called bioactive peptides (5). The physical stability of emulsions containing bioactive ingredients is an important aspect for the functional development of foods. There are a few studies on the foaming properties of peptide solutions, which are of interest for the study of selective peptide extraction systems due to the connection between their surfactant properties and their physicochemical state (6, 7). Larre *et al*. (8) compared the foaming properties of several hydrolysates obtained from rapeseeds at different pH levels. The hydrolysates obtained by basic chemical hydrolysis and pepsic hydrolysis showed different peptide populations, but their foaming properties were optimal at 3% hydrolysis degree in both cases. Perez A.A. (9) investigated the foaming properties of several hydrolysates with various hydrolysis degrees (5.6, 23.5, 45.3). Increasing the hydrolysate concentration leads to an increase in foaming capacity and to a more stable foam.

Our research investigated the effects of various peptide populations with different hydrophobic characteristics on the surface tension of hydrolysates obtained from bovine hemoglobin. Bovine hemoglobin was selected because it is inexpensive, easily available, well-characterized, and has been used in numerous studies (10-15).

MATERIAL AND METHODS

Solution preparations

The 14.36% hemoglobin solution was prepared by dissolving the corresponding amount of bovine hemoglobin powder (Sigma, ref. H2625) in 100 mL distilled water, which was then centrifuged at 4000 rpm to remove the insoluble portion.

The pepsin stock solution was prepared by dissolving 100 mg pepsin in 20 mL distilled water.

A 5M sodium hydroxide solution was also used.

Peptic hemoglobin hydrolysis

Hydrolysis was performed on a 1% (w/v) hemoglobin solution obtained by diluting the 14.36% hemoglobin solution.

50 mL of 1% (w/v) hemoglobin solution (adjusted to pH = 3.0 with 1M HCl) was mixed with 10 mL pepsin solution (3200 AU/mg) corresponding to a 2.5% (w/v) enzyme/substrate ratio. Hydrolysis reaction was stopped after 2.5 min, using the 5M NaOH solution, in order to adjust the pH at 9.5 that inactivates pepsin. 10 h- and 120 h- hydrolysates were obtained under the same conditions. All hydrolysates were filtered through 0.45 μm cellulose acetate filters, and then analyzed by reverse phase high performance liquid chromatography (9, 10).

The HPLC system used included a Wa-

ters TM 600 pump controller and a Waters 996 diode bar detector. A Vydak C4 column (0.46×25 cm) was used for separation. The mobile phase consisted in an A eluent containing water and trifluoroacetic acid (TFA) in a 1000:1 (v/v) ratio, and a B eluent composed of acetonitrile, water, and TFA in a 600:400:1 (v/v) ratio at a flow rate of 1 mL/min. The gradient applied was 0-67% (v/v) B over 30 minutes, then 67–87% (v/v) B over 35 minutes (11). UV absorbance scans were performed between 200 and 300 nm.

Surface tension measurement

Surface tension between the aqueous phase containing the peptides and air was measured in order to determine the surfactant properties of various hydrolysates. A KRUSS DSA 10Mk2 tensiometer was used. The first drop of solution that was formed was neglected and the measurements were made on the second drop.

After droplet suspension, surface tension measurements were done after 5 minutes, time required for peptides that have surfactant properties to position themselves at the water/air interface in a stable manner. In order to obtain a stable and reproducible measurement there was a 30-minute waiting time. The tensiometer was connected to a data station that recorded the data and calculated the surface tension depending on the droplet shape. Surface tension of the unhydrolyzed hemoglobin solution and 2.5 min-, 10 h-, and 120 h-hydrolysates was measured.

RESULTS AND DISSCUSION

Hydrolysis was performed on bovine hemoglobin in native state. Figure 1 shows the chromatographic profiles of hemoglobin used to obtain the hydrolysates, where hem molecules were revealed at a 38-minute retention time, while the alpha and beta molecules were detected at retention times between 40 and 50 minutes.

Once the hydrolysates were obtained, the reaction was stopped after 2.5 min, 10 h and 120 h respectively, using the 5M NaOH solution. The chromatographic profiles of the hydrolysates (figs. 2-4) revealed a wide variety of peptides. The 2.5 min-hydrolysate showed a peptide population with retention time between 20 and 36 minutes. There were large peptides with highly hydrophobic surfaces. The hem was detected through chromatography at 38 minute- retention time. Those peptide fractions were not found in the other two hydrolysates. In the 10- and 120 h-hydrolysates, the peptides were smaller and more hydrophilic. The hem was detected in the chromatogram at a 35 minute-retention time. Those results showed that by increasing the hydrolysis time, smaller peptides were produced.

We have observed that the hem in all analyzed sample was not degraded by pig pepsin. Hemoglobin chains were hydrolyzed in order to obtain peptide hydrolysates containing various peptides from the initial protein based on their molecular weight, number of ionizable sites, and surface hydrophobicity.

Figure 5 shows the comparative results obtained during the measurements of surface tension as well as the evolution of surface tension for nonhydrolyzed hemoglobin and hydrolysates.

The process of hydrolysis influenced the surface tension of the solutions. It was found that hydrolysates exhibited lower surface tension compared with nonhydro-

lyzed hemoglobin. Also, the 10- and 120 h-hydrolysates had a distinct profile compared to the 2.5 min-hydrolysate, which led to the conclusion that hydrophobicity and peptide size were important parameters that influenced surface tension.

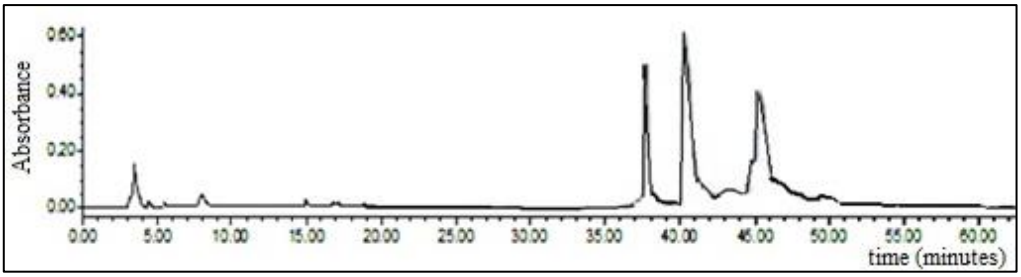

Fig. 1. Chromatographic profiles of hemoglobin

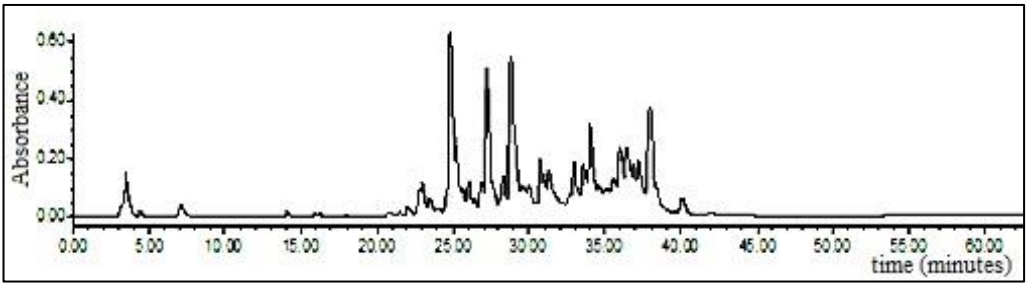

Fig. 2. Chromatographic profiles of 2.5 min-peptide hydrolysate

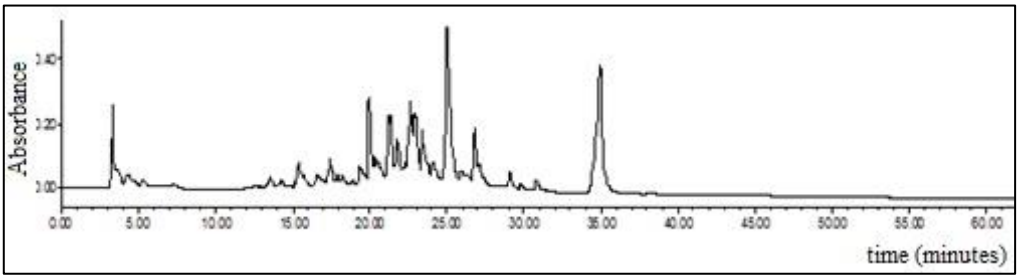

Fig. 3. Chromatographic profiles of 10 h-peptide hydrolysate

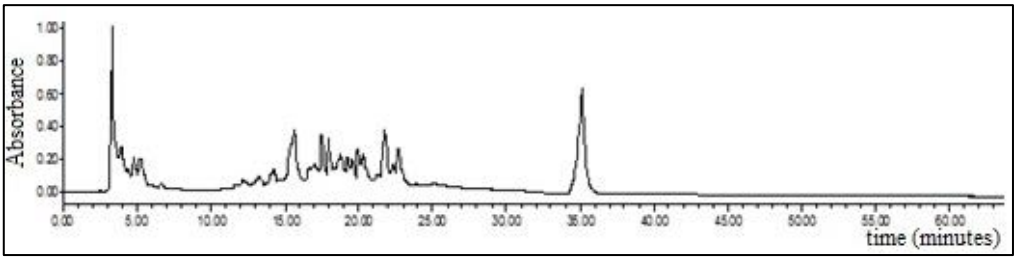

Fig. 4. Chromatographic profiles of 120 h-peptide hydrolysate

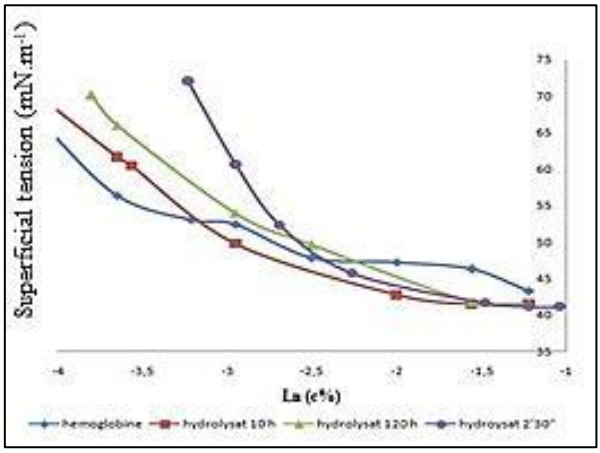

Fig. 5. Evolution of surface tension depending on the concentration of nonhydrolyzed and hydrolyzed bovine hemoglobin

The correlations between chromatographic profiles and stress curves showed that high hydrophilicity resulted in lower values of surface tension that translated into a better affinity of peptide populations to the air/liquid interface. For the hydrolysates, it was noticed that at low concentrations the surface tension values were distinct, while at higher concentrations they tended towards the same value. The surface tension of the nonhydrolyzed hemoglobin solution stabilized around 40 $mN.m^{-1}$, which was similar to other studies (11, 15).

CONCLUSIONS

In the present study, we have obtained peptide hydrolysates through bovine hemoglobin hydrolysis using pepsin. We have used droplet tensiometry to investigate the surface tension between air and the aqueous phase containing the peptides. The hydrolysates presented lowersurface tension values than nonhydrolyzed hemoglobin, meaning that the presence of peptide population reduces the surface tension. Therefore, further studies are needed to determine the critical micelle concentration or hydrophilic-lipophilic balance value indicating the surfactant properties of the peptides. These studies will also allow us to determine the optimal concentration of a hydrolysate required to achieve stable surfactant properties.

NEWS

CARDIAC AMYLOIDOSIS: WHAT'S NEW, WHAT'S OLD

AND WHAT SHOULD WE EXPECT

New perspectives for diagnosing cardiac amyloidosis using especially the imagistic part of this illness are under research. From a symptomatic point of view, till present time there are no new discoveries. The same symptoms that were previously discovered are also present today. Advancements in the imagistic part offers perspectives by using cardiac MRI, bone scintigraphy and PET. Imagistic presents an easy path for diagnosing cardiac amyloidosis. MRI presents new perspectives for understanding pathophysiological processes. Furthermore, MRI can detect and diagnose cardiac amyloidosis but cannot differentiate the subtype involved. Bone scan has almost completely reduced the need for cardiac biopsy, by detecting, diagnosing and even differentiating the subtype of cardiac amyloidosis involved. PET can quantify cardiac and extracardiac amyloid burden, but this method is still being studied (L. Chacko, R. Martone, F. Cappelli, M. Fontana. Cardiac Amyloidosis: Updates in Imaging. *Curr Cardiol Rep* 2019; 21: 108).

STUDY ON THE BENEFITS OF USING DIAGNOSTIC WAX-UP IN DENTAL TREATMENT

STUDY ON THE BENEFITS OF USING DIAGNOSTIC WAX-UP IN DENTAL TREATMENT (Abstract) The diagnostic wax-up is a representation of the future prosthesis, allowing the patient's checking and adaptation with the shape, color and position of the future prosthetic appliance, prior to the treatment being executed. It offers the possibility of the patient's active intervention in order to perform the prosthetic work and, with its help, the functional recovery and the correct evaluation of the occlusal rapports can be verified. **Material and methods**: This paper is a prospective study on a batch of 103 patients, who came to the dental practice and who were questioned, in order to evaluate the necessity to introduce the diagnostic wax-up into the prosthesis algorithm. The modality of obtaining the data was by the accounting of the information obtained after the answers to a questionnaire; the data obtained from the questionnaires were statistically interpreted by using *SPSS version 14* program. **Results**: the results show that most of the patients (96%) consider the diagnostic wax-up to be useful as a communication tool with the dentist. However, there are patients who are reluctant (8%); the patients believe that the communication with the dentist can be improved which would lead to the increase in the satisfaction degree regarding the dental prosthesis in the oral cavity. **Conclusions**: Following this analysis, it can be concluded that diagnostic wax-up will become an indispensable tool in the dental practice and its advantages recommend it as a compulsory stage in the complex oral rehabilitation. **Keywords**: DIAGNOSTIC WAX-UP, PROSTHETIC APPLIANCES, FUNCTIONAL REHABILITATION.

The prosthetic rehabilitation involves the restoration of the functions of the dental-maxillary system and the re-establishment of a new dental-somato-facial balance.

In order to improve the dentist-technician-patient communication, in order to obtain appropriate results, it has been imposed a technological stage included in the first phase of the clinical-technological algorithm: the diagnostic wax-up (1). The assessment of the treatment needs for every patient is a routine procedure in the dental practice. The estimation may vary from one practitioner to another and represents a complex aspect and sometimes even inconsistent between the clinical reality and the patients' expectations, who are often unable to estimate the limitations imposed by the features of the prosthetic field and who do not have the ability to predict the final re-

sult. The diagnostic wax-up allows, besides the radiological exploration and the preliminary footprint, heading towards a treatment plan and offering the patient a clear and correct perception upon the real situation.

Used for decades, the diagnostic wax-up is nowadays able to assure a prosthetic rehabilitation at the highest aesthetic, morpho-functional and biological standards due to the versatility of its uses. The achievement of the diagnostic wax-up involves the prefiguration of the final results from the very first phase, as well as the adjustment of the treatment plan and the patient's active intervention in achieving the prosthetic work. With its help, one can evaluate the aesthetics, phonetics and functionality of an oral rehabilitation or to evaluate and correct the occlusion in the case of a mandibular cranial mal-relation. This diagnostic wax-up is successfully used in prostheses by direct and indirect techniques or in temporary prosthesis and it can function as an operating pattern in the preparation of organic substructures or even in implantology. A strong advantage is the fact that it allows the optimization of the cervical adaptation of prosthetic restorations obtained by computerized technologies. Dentists agree that the success of the dental treatment consists not only of perfect technological execution, but also requires a detailed planning of the treatment. Thus, it is found that the analysis of the study layout is not enough in obtaining a successful final result, which is why the intermediate pieces have been imposed - the diagnosis models. More and more often, trial layouts are sent to the dental technique laboratory so that the technician will perform diagnosis layouts in order to visualize the finality of the proposed treatment plan. Sometimes, these layouts are used for emergency prosthesis performed by the indirect technique (2). Unlike the temporary prosthetic pieces obtained by the direct technique in the dental practice, the prostheses achieved in the laboratory have an increased resistance to the pressure and traction forces and have a superior functional rehabilitation.

The purpose of using the diagnostic wax-up is for the patient to visualize the future prosthetic solution, a better communication with the dental technician, a clinical examination upon the adaptation and oral integration of the prosthetic construction. (3,4). The layout process from diagnosis wax is not a frequently used clinical-technological stage but it should be taken into consideration at the onset of every dental treatment, as it involves improving the patient-physician communication by actively involving the patient in establishing, modifying, or adjusting the therapeutic solution, improving the dentist-technician communication, the evaluation and correction of occlusion, the composing of an operator guide in order to correctly prepare the organic structures, the evaluation of aesthetics, functionality, operator guide for applying implants, the optimization of cervical adaptation in CAD CAM technology (5). According to the desired type of diagnostic wax-up of the dental technique laboratory, special waxes or white monochrome waxes can be used. This wax has various properties of common wax used in the layout process, whether parchment wax or for crowning. The analysis of the advantages and disadvantages is upon the dentist's discretion, who will establish the material used in the therapeutic strategy (6).

MATERIAL AND METHODS

In this paper, we performed a prospective study on a batch of 103 patients, aged between 19 and 80, who came to the dental practice with functional disorders. After the

clinical examination, the establishment of the diagnosis and the therapeutic strategy, we explained the utility of introducing in achievement algorithm of the dental prosthesis belonging to layout process stage diagnosed in the dental treatment. In the study protocol, we specified the aim and the field of research (the evaluation of the necessity to modify the clinical-technological algorithm for performing the prosthetic works) having as an objective the study of the correlations between different parameters. For this purpose, the patients filled in a questionnaire including the following: full name, age, sex, job, regularity of the visits made to the dentist, food preferences, the awareness of the importance to maintain the natural teeth on the arcade, knowing the limits of prosthetic restorations, the communication with the dentist, informing on the diagnostic wax-up, interest in getting involved into the knowledge of the treatment stages and the utility of the diagnostic wax-up, the desire to integrate the diagnostic wax-up in the current dental treatment.

The patients were informed that the aim of this questionnaire is to assess the necessity to introduce a new stage – the diagnosis layout – within the dental treatment and were assured that the information is confidential.

The data obtained after filling in the questionnaires were accounted and statistically interpreted by the SPSS program 14. According to the defined variables, we introduced every person's data who filled in the questionnaire and we obtained a table with 103 lines and 13 columns.

In order to express the centralized data with the aid of questionnaires, we used frequency tables expressed as graphics. Thus, we can create an overall image upon the information that will be used to observe correlations.

RESULTS

A first analyzed aspect was whether patients had any knowledge about this treatment stage and about its utility. Thus, we found that almost 55% of patients had information about the diagnostic wax-up (fig. 1) and 95% considered it extremely useful for the therapeutical success (fig. 2).

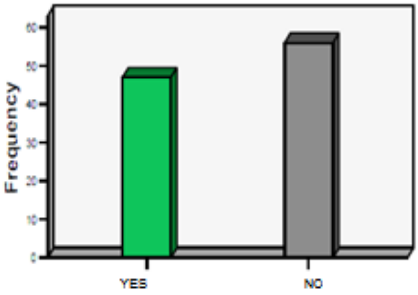

Fig. 1. The comparative diagram with patients who had information about the diagnostic wax-up previous to the filling in of the questionnaire

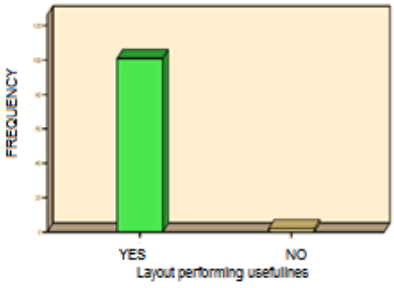

Fig. 2. The comparative diagram with patients who considered the layout performing useful in the dental treatment

A second aspect that we looked for was whether patients thought that diagnostic wax-up improve the communication with their physician and whether they want to

introduce this stage into the working algorithm. 93% of the respondents stated that in the diagnostic wax-up stage they had a clear image of the future prosthetic work and were able to intervene with suggestions on making morphological or color changes, which definitely improved the doctor-patient collaboration (fig. 3). Also, 96% of respondents agree to make the diagnostic wax-up before the onset of the prosthetic treatment.

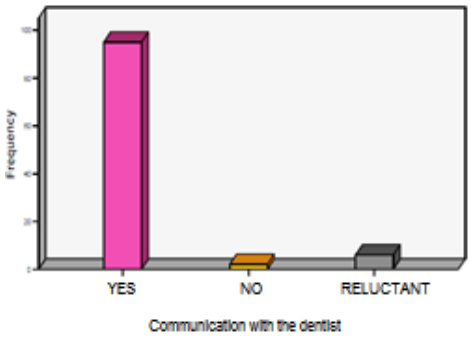

Fig. 3. The comparative diagram with patients who consider useful making the diagnostic wax-up for improving the communication with the dentist

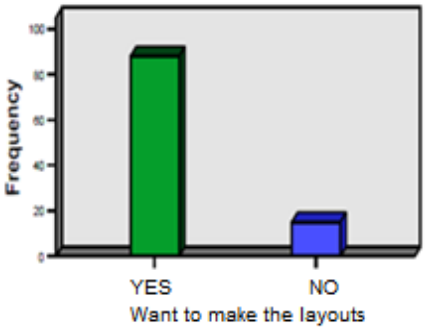

Fig. 4. The comparative diagram with patients who want to make the layouts before the onset of the prosthetic treatment

DISCUSSION

Besides the awareness effect upon the population regarding the existence of diagnostic wax-up, the comparative study of the variables included has proven that: most patients find the diagnostic wax-up useful as a communication tool with the dentist, however, there are reluctant patients (8%); patients believe that the communication with the dentist can be improved, which would lead to the increase in the satisfaction degree on the dental prostheses applied in the oral cavity (7).

In the study batch, the major aesthetic requests showed around the age of 24, and the disinterest in the aesthetic aspect of the dental rehabilitation is seen between the age of 60-80. The highest numerical values of those satisfied/dissatisfied with the dental treatment are around the age of 25; the major interest in maintaining the natural teeth on the arcade is noticed at the age of 22, progressively decreasing with the age.

There is a comparable percentage (59 41%) about the achievement of a diagnostic wax-up before the onset of the prosthetic treatment for dental prostheses and the achievement of diagnostic wax-up to determine the possibilities of aesthetic and functional improvement in the case of people without prostheses (fig. 5).

Although there are many patients who find useful the diagnostic wax-ups and want them to be done, there are also patients who find them useful but do not want their dental technician to create them (fig. 6)

The better the collaboration with the dentist and the dental technician, the more functional and aesthetic the prosthetic reconstruction will be, the patient will adapt much better to the artificial substitute and the social integration is faster (8) (fig. 7).

Most patients who have prostheses and

have been satisfied with the applied treatment agreed with the utility of performing the diagnostic layouts as intermediate therapeutic stage (fig. 8).

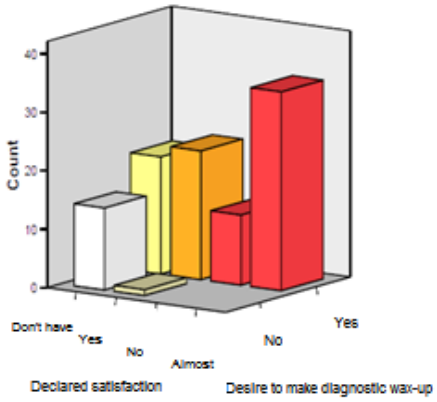

Fig. 5. The correlation between the satisfaction declared by patients about the dental prostheses and the desire to make diagnostic wax-up

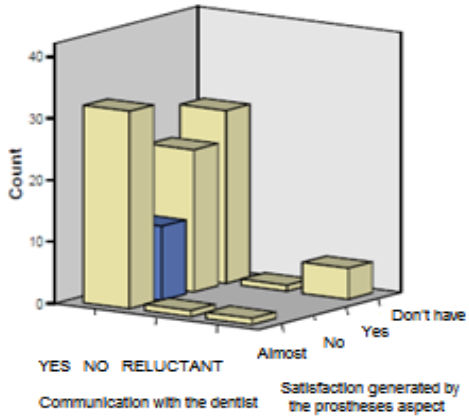

Fig. 6. The correlation between the communication with the dentist and the satisfaction generated by the prostheses aspect

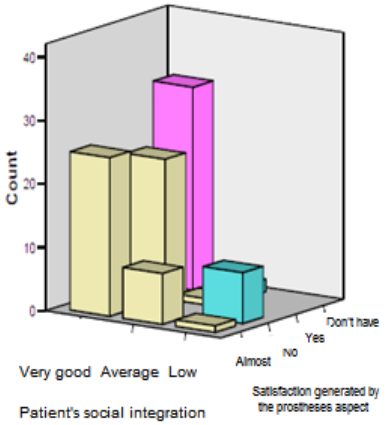

Fig. 7. The correlation between the patient's social integration and the satisfaction generated by the prosthetic piece in the oral cavity

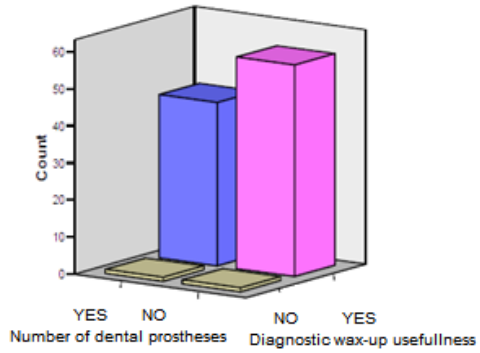

Fig. 8. The correlation between the number of patients who find the diagnostic wax-up useful and the number of dental prostheses

CONCLUSIONS

After the completion of the building stage of diagnostic wax-up, the following aspects could be specified in detail: the necessity to adjust the treatment plan, the modification of the occlusal relief in relation to the particularities of the clinical case, the modification of the chromatic or morphological parameters in relation to the patient's desires.

Supported by the statistical study, whose results prove that most patients de-

sire the creation of the diagnostic wax-up, this clinical-technological stage is very useful in implementing a therapeutic plan because it represents a communication method that allows the patient, the dental technician and the dentist to manage the complex prosthetic cases.

The diagnostic wax-up will increase the predictability degree of the final result, reducing the time that the patient spends in the dental practice while avoiding disagreements at the end of the treatment.

It also allows the creation of oral changes before the onset of the treatment plan, thus increasing the functionality of the finished prosthetic piece and guaranteeing a satisfying result of the treatment.

This intermediate piece predicts the therapeutic result and allows the patient to have a clearer explanation regarding the possible limits of the rehabilitation therapy.

The technology of creating the diagnostic wax-up is relatively easy to learn by dental technicians, and the appearance of digital layout technologies on the market substantially reduces the time allocated to this diagnostic wax-up provides the possibility of adjustments to restore the aesthetic function, under visual control, in the oral cavity both during rest and during exercising functions. With their help, temporary dental prostheses can be created, which increase the patient's compliance with the prosthetic treatment (9).

The patients will always accept more easily a prosthetic construction that they have seen in progress.

The questionnaires allowed us to obtain the patient's informed acceptance and his/her active involvement in dental prosthesis, with a better communication, an increased level of confidence in the dentist and an increased satisfaction at the end.

Taking into consideration the characteristics of the diagnostic wax-up, it can be stated that this will become an indispensable tool in the dental practice, its advantages indicating it as a usual stage in the clinical-technological algorithm of creating the complex oral rehabilitation.

CARDIAC RESPONSE AS STRESS MARKER IN SURGERY (Abstract): Surgical area - as a precursor of negative emotions, is the threshold between the two areas of anxiety and anxiety among the general and specific stimuli. By dominant color, noise, odors and environmental factors in complex anxiety these elements define the specific treatment of dental medicine better. The emotional stress on the patient child which undergoes a surgical dento-alveolar therapy is negative and consists of the combination of three important elements, in close relationship: score of dental anxiety, the anticipation and experience of pain and phobic stimuli which is implicitly true precursor of pain. **Material and method**: Our study was performed on 448 patients. Different methods of preanesthesia were made per oral, intravenous, intramuscular, according with DAS score: Midazolam, Diazepam + Algocalmin, Xanax. **Results**: 58% of our patients declare after surgery that their satisfaction score is 100% positive after one of our method of preanesthesia. **Conclusions**: The purpose of premedication should be unconditionally determined by the effect of the analgesic and anxiolytic drugs to improve cardiac response and avoid medical emergency. Doses administered must be correlated with the anxiety score DAS, road use and the probable duration of surgery. **Key words**: PAIN, ANXIETY CONTROL, PREANESTHETICS DRUGS, CARDIAC RESPONSE

CHEMICAL PERSPECTIVE ON ANTI-AGING PROPERTIES OF SOME PHENOLICS FROM PLANTS

CHEMICAL PERSPECTIVE ON ANTI-AGING PROPERTIES OF SOME PHENOLICS FROM PLANTS (Abstract): Nowadays it is well-accepted that topical polyphenol-rich products can reverse partially the clinical and histological changes in the epidermis and dermis induced by the combination of sunlight exposure and chronologic aging. Natural compounds used against photoaging comprise phenolic compounds, including flavonoids, phenolic acids (benzoic, gallic, cinnamic acids) and stilbenes derived from plants such as tea, grape, bergamot, rooibos, grapefruit, red orange. It was reported that many polyphenols from plants exhibit inhibitory activity against collagenases and elastases. Phenolic derivatives are efficient protectors through reduction of oxidative stress, inflammation and immunosuppression and may be important components in cosmetic formulations. **Keywords**: POLYPHENOLS, SKIN, ANTI-AGING.

Skin is a structure subject to an unpreventable intrinsic aging process. Skin aging is a biological process, complex, progressive and inevitable characterized by atrophy of the skin with loss of elasticity and slowed metabolic activity. Skin aging is characterized by signs as: wrinkling, dryness, laxity, scaling, roughness, hyperpigmentation etc (1, 2).

One of the major features of skin aging is the progressive proteolytic degradation of cutaneous elastic fibers that cannot be suitable replaced by adult dermal fibroblasts (3).

An overproduction of ROS depletes physiological levels of ROS-scavenging enzymes (such as superoxide dismutase (SOD) and catalase), resulting in damage to proteins, lipids and even DNA, and premature photoaging and skin diseases (4, 5).

Reactive oxygen species (ROS) are normally produced in cell metabolism but, when the balance between free radicals and antioxidants is unbalanced, these chemical species can participate to a pathological process known as oxidative stress.

In fact, the oxidative stress is involved in skin aging, the lipid peroxides level being a good parameter to determine the oxidative stress. Superoxide dismutase (SOD) and catalase increases with chronologic aging and they could have been considered as important markers of oxidative stress.

The main process in the skin aging are represented by the intracellular and extra-

cellular oxidative stress initiated by two main events: the formation of ROS and the induction of matrix metalloproteinases (6).

The formation of free radicals which can react with DNA, proteins, sugars and fatty acids can causes oxidative damage and it is a widely accepted that this mechanism causing skin aging by inducing wrinkling, elastosis, drying, roughness, appearance of fine lines, lack of elasticity and hyperpigmentation marks.

The induction of matrix metalloproteinases leads to the accumulation of fragmented collagen fibrils, which prevents neocollagenesis.

Aging is accelerated to sunlight exposure (ultraviolet radiation), a process known as photoageing. It is called photoageing because of a combination of short wavelength (UVB) injury to the outer layers of the skin (epidermis) and long wavelength (UVA) injury to the middle layers (dermis).

UV radiation is absorbed by skin molecules and generates ROS that determine "oxidative damage" for cellular components like cell walls, lipid membranes, mitochondria and DNA. Each UV exposure induces a wound response with subsequent imperfect repair, leaving an invisible "solar scar" repetitive UV exposure eventually lead to development of a visible "solar scar" manifesting as a visible wrinkle over a lifetime. Exposure to UV irradiation induces photochronical generation of ROS that activates cell surface growth factors, cytokine receptors and NADPH oxidase (7, 8). This process induces signal propagation within the cell through phosphorylation of tyrosine residues on the receptors and their associated adaptor proteins. Two nuclear transcription factors are activated: activator protein 1 (AP-1) and nuclear factor-κB (NF-κB), involved in transcription of genes for matrix-degrading enzymes and proinflammatory cytokines (9,10). These transcription factors are associated with skin dryness, pigmentation, laxity, deep wrinkling (11,12).

CHEMICAL CLASSIFICATION OF PHENOLIC COMPOUNDS

Plants are a good source of important products with therapeutic value. There is emerging evidence that topical application or oral intake of some polyphenol-rich plant extracts can reduce the skin aging process.

Phenolic compounds are characterized by the presence in their chemical structure an aromatic ring linked to a hydroxyl group, which has a great ability to donate electron and hydrogen, structural features important for their exceptional antioxidant activities.

Polyphenolic compounds have been extensively studied and are found in several plants including tea leaves (*Camellia sinensis*), grape seeds (*Vitis vinifera*), blueberries (*Vaccinium myrtillus*), almond seeds (*Prunus amygdalus*), pomegranate extract (*Punicagranatum*).

Phenolic compounds comprise one or more aromatic rings and have one or more hydroxyl groups. They are usually found as esters or glycosides rather than as free compounds, and mostly are present as conjugates with mono- and polysaccharides, linked to one or more of the phenolic groups. The term "*polyphenol"* includes a large group of substances, which have more than one phenolic hydroxyl group, bounded to one or more benzene ring systems (13).

The classification and structure of the phenolic compounds are presented in first figure (14, 15).

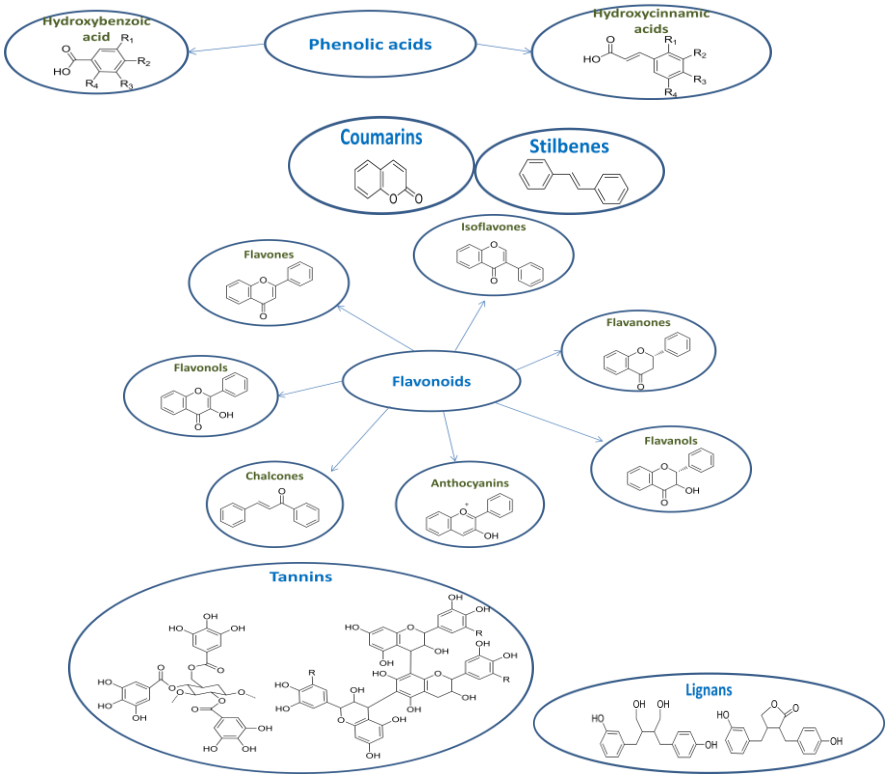

Fig. 1. Classification of the main phenolic compounds

NATURAL PHENOLS IN SKIN AGING PROCESS

The beneficial effects of polyphenols as functional ingredients have attracted considerable attention of the pharmaceutical and cosmetic industry in the last period of time. As a consequence, many skin care products have been developed based on polyphenol-enriched plant extracts. To exert their designated biological activities, topically applied substances have to be able to be released from the formulation, to reach the skin and finally to overcome the stratum corneum barrier and penetrate into the epidermis and dermis. The release of active substances and further skin permeation depends on the molecule properties such as molecular weight and lipophilicity but also on the vehicle formulation (16).

Consumers prefer to use more natural compounds on their skin. Thus, plant phenolic compounds are a promising target for new dermal cosmetics that possess the ability to maintain the skin homogeneity and a proper, healthy look due to effective skin cell renewal, elastin and collagen stimulation and inhibition of excessive melanin synthesis.

A lot of topical treatments for skin aging incorporate antioxidants. They scavenge free radicals and are known to contribute to the physiological effect on skin health, having a anti-wrinkle effect.

Topical application of antioxidant ac-

tive substances can support the skin's own antioxidant system against oxidative stress and could protect the skin against photoaging.

Most of the natural polyphenols can absorb UV radiation. Therefore, when applied topically, they can prevent penetration of the radiation into the skin. This ability of natural polyphenols to act as sunscreens can reduce inflammation, oxidative stress and DNA damaging effects of UV radiation in the skin and, thus, on topical application the photoprotective effects of polyphenols are due in part to this sunscreen effect.

The chemical structure of polyphenolic compounds is correlated with their reducing properties, which allow them to act as antioxidants and free radical scavengers. The antioxidant activity of flavonoids is essentially determined due to substitutions on rings B and C, for example the number and positions of hydroxyl groups in the B-ring as well as double bonds and substitutions in the ring C.

Phenolic extracts are found to inhibit the activity of proteinases, which catalyze the degradation of skin proteins, such as collagen and elastin. Collagen in the dermis is responsible for the firmness, elastin fibers lend the elasticity. An excessive ROS formation provokes the expression of collagenase (MMP-1) and elastase, leading to an accelerated degradation of corresponding proteins.

One of the best sources of phenolic antioxidants is tea (*Camellia sinensis* L.), especially green tea but also black tea, oolong tea and white tea, which possess great antioxidant properties.

The majority of the green tea polyphenols are monomeric flavanols known as catechins. The major catechins found in green tea are: catechin (C), epicatechin (EC), epigallocatechin (EGC), epicatechin-3-gallate (ECG), epigallocatechin-3-gallate (EGCG), gallocatechin-3-gallate (GCG). Green tea catechins are characterized by dihydroxy or trihydroxy groups on the B ring and the meta- 5,7-dihydroxy groups on the A ring, with the B ring appearing to be the principal site of antioxidant reactions. Such antioxidant activity is further enhanced by the presence of a trihydroxy structure in the D ring (gallate) in ECG, EGCG and GCG (17).

Besides tea, grape (*Vitis vinifera* L.), one of the largest fruit crops in the world, is an important source of polyphenols. The antioxidant activity of grapes seems to be depended on the color of the berries; dark fruits have higher antioxidant capacity than the white ones, because the content of anthocyanins and flavonoids increases with increasing color intensity of grapes. Apart from catechin, epigallocatechin and epigallocatechin-3-gallate, resveratrol was also found in grape skin. Antioxidant activity of plant extracts often correlates with the total phenolic content (18). However, the polyphenol profile also determines the effectiveness of extracts, as the activity of individuals substances varies strongly, caused by the differences in the chemical structure.

The high antioxidative activity of grape or tea extracts is derived from a combination of several active substances, which results in an increased activity due to some synergistic effects.

It was reported that many polyphenols from plants exhibit inhibitory activity against collagenases and elastases. During aging, the extracellular matrix proteins are susceptible to excessive activity of proteolytic enzymes-matrix metalloproteinases (MMPs).

The scientific literature highlights the efficacy of polyphenols as topical anti-

aging agents (resveratrol, EGCG, genistein).

Epigallocatechin-3-gallate (EGCG), a compound from green tea is effective in improving the skin condition by the reactivation of the damaged or old cells due to the DNA protection and production of more energy in the cells.

Topical treatment of the mouse and human skin with EGCG prior to UV exposure significantly reduced UVB-induced nitric oxide and hydrogen peroxide production.

Green tea polyphenols can be considered as inhibitors of both tyrosinase activity and expression in melanocytes, thereby inhibiting melanin production induced by UV irradiation. These compounds exert antiwrinkle effects through collagenase by affecting both direct enzyme activity and physical volume.

The steric structure of the 3-galloyl radical of catechin is very important for the inhibition of collagenase activity (19). EGCG has an additional galloyl unit and hydroxyl groups compared to catechin and, thus, can engage in better hydrogen bonding and hydrophobic interactions with collagenase, inducing significant changes in its conformation that result in potent inhibition (20). EGCG and ECG bind to collagen through extensive hydrogen bonding augmented by hydrophobic interactions, preventing the free access of collagenase to active sites on the collagen chains (21).

EGCG is a potent scavenger of ROS with exceptionally strong antioxidant activity. Similarly, Roh *et al.* (22), suggested that the ortho-trihydroxyl group in the B ring and the galloyl moiety at the 3-position of the flavan-3-ol skeleton of ECG and GCG are the most important structural requirements for the free radical scavenging effects. ECG also acts as a free radical scavenger on photodamaged keratinocytes.

EGCG or green tea polyphenols added to hydrophilic ointments inhibit UVB-induced oxidative stress through MAP kinase signaling pathways (22).

Green tea polyphenols act as antiaging compounds. EGCG and epicatechin-gallate are the major polyphenolic components capable to act as antioxidants *in vitro* by scavenging reactive oxygen and nitrogen species and chelating redox - active transition metal ions.

According to Katiyar's studies, EGCG reduces UV-induced erythema and sun burn cell formation and green tea polyphenols have an important role in reduction of UVB-induced pyrimidine dimmer formation in epidermis and dermis (23).

It is well known that excessive and chronic exposure of the skin to UV radiation can overwhelm the cutaneous antioxidant capacity, leading to a premature aging of the skin. Polyphenols from green tea have been shown to inhibit photo-enhanced lipid peroxidation. Topical treatment of the mouse and human skin with epigallocatechin-3-gallate (EGCG) prior to UV exposure significantly reduced UVB-induced nitric oxide and hydrogen peroxide production. It is well established that the infiltrating leukocytes is the major source of nitric oxide and hydrogen peroxide production. EGCG has been shown to have the ability to block UVB-induced leukocyte infiltration in mouse as well as in human skin, and thus may be able to inhibit UVB-induced production of reactive oxygen species by these infiltrating leukocytes. Wei *et al.* (24) have demonstrated that aqueous extracts of green tea have potent scavenging effects on reactive oxygen species.

Resveratrol (3, 4', 5-trihydroxy-trans-stilbene is a polyphenol that exists in two isomeric forms, 3, 4', 5-trihydroxy-cis-stilbene and 3, 4', 5- trihydroxy-trans-

stilbene, the *trans* form being biologically active.

Resveratrol functions as an antioxidant in several ways. It serves as a free radical scavenger that effectively quenches reactive oxygen species such as hydroxyl, superoxide and metal-induced radicals. Topical application of resveratrol has been proven to protect against UVB-mediated skin damage (25).

Specific polyphenol receptor sites have been identified in the skin that bind resveratrol, which then exert protection against the nitric oxide free radical donor sodium nitroprusside (26).

Resveratrol is reported to stimulate healthy cell proliferation as well as collagen synthesis by protecting the dermal matrix from harmful enzymes and improving the function of fibroblasts that produce healthy collagen.

Resveratrol has been shown to be active in neutralizing and inhibiting the formation of reactive oxygen species but *in vitro* conditions, is an effective neutralizer of synthetic DPPH radicals (8).

In vitro studies using the oxygen radical absorbance capacity (ORAC) test showed that resveratrol has 17 times higher antioxidant activity (4,845 μmols vitamin E/g) compared to the synthetic coenzyme Q10-idobenone (279 μmols of vitamin E/g) (9). In contrast, the antiradical activity of resveratrol relative against to peroxide radicals was higher than catechins, gallic acid and ellagic acid (10).

Resveratrol can also protect skin from photo-aging. In *in vivo* studies on hairless mice, it was observed that the single application of resveratrol before UVB exposure significantly reduced skin edema and reduced the UVB induced H_2O_2 production and also could limit lipid peroxidation and reduce leukocyte infiltration.

Resveratrol can successfully affect the protection of human keratinocytes by limiting the expression of NF-κB transcription factor and phosphorylation and degradation of IκB triggered by UVB radiation (27, 28).

In addition, *in vitro* studies using HaCaT cell lines have demonstrated that resveratrol protects keratinocytes against UVA radiation. Under the influence of UVA radiation and other stressors, free radicals and reactive oxygen species, especially superoxide anion and hydrogen peroxide, lead to oxidative stress (25).

The antiaging effect of resveratrol was also observed in clinical studies. During a 12-week clinical trial of 55 women aged 40-60 years old, it was observed that the use of night cream containing resveratrol (1%), baicalin (0.5%) and vitamin E (1%) could improve the skin condition, by limiting the changes caused by the photoaging process. Clinical evaluation showed statistically significant improvement in skin firmness and elasticity, smoothing fine wrinkles and reducing discoloration after 12 weeks (29).

It was found that resveratrol increased dermal and epidermal thickness through impact on greater collagen production, which may increase skin firmness and elasticity and lead to skin rejuvenation as well as wrinkle reduction (30).

Resveratrol cannot be considered as an inhibitor of tyrosinase as a substrate. Moreover, this substrate seems to be converted by tyrosinase into an inhibitor and even if oxyresveratrolacts as a non-competitive inhibitor of tyrosinase with L-Dopa, resveratrol is nevertheless able to occupy the L-dopa site. Resveratrol is a "suicide substrate" for tyrosinase.

One of functions of antiaging products is to prevent the formation of senile lentigines and solar lentigo. Hence, the possi-

bility of influencing tyrosinase activity by resveratrol is of great importance and practical application in the field of antiaging preparations whose function is to prevent the hyperpigmentation (25, 31).

In vitro studies showed that the percentage of resveratrol found in the stratum corneum after permeation was however very low, about 5% of the total applied, but still enough to cause a significant impact on the epidermal antioxidant capacity (32).

Quercetin is a flavonoid that has antioxidant effects, being able to influence cellular viability, lifespan and presenting rejuvenating effect on culture of senescent fibroblasts. Also, this polyphenol has the ability to block ultraviolet irradiation induced inflammation viaNF-κB inactivation on primary keratinocytes (33). Quercetin provided inhibition of matrix metalloproteinase activity and it can be considered an agent with a role in protection of skin collagen from destruction during inflammatory response to extrinsic aging factors (34).

Quercetin shows water solubility and it has a partition coefficient of 1.82 ± 0.32 due to the presence of nonpolar groups in its structure. But despite this log P value, quercetin polar hydroxyl groups hinder its skin penetration capacity (35).Due to its poor solubility, quercetin has limited skin penetration ability and various formulation approaches were taken to increase its dermal penetration.

CONCLUSIONS

Natural polyphenols possess scavenging properties towards radical oxygen species that make them interesting for antiaging purposes in cosmetics formulations skin care.

Polyphenols structures are active ingredients capable of counteracting symptoms of epidermal aging, can improve solar radiation protection and epidermal antioxidant activity and they have been considered important ingredients for anti-aging cosmetic formulations.

Topical antiaging products formulated with polyphenolic components make extensive claims to reduce wrinkles, fine lines and sun damage and their sales are expected to increase, based on the consumer interest in health and enhance the growth of this segment of the market due to the demand of the population opting for less invasive, non-surgical alternatives to slow the effects of aging on the skin.

MICROENVIRONMENT IN COLORECTAL CANCER

Transforming growth factor-beta (TGF-β) signaling is one of the important cellular pathways that play key roles for tissue maintenance. In particular, it is important in the context of inflammation and tumorigenesis by modulating cell growth, differentiation, apoptosis, and homeostasis. TGF-β receptor type 2 (*TGFBR2*) mutations affected by a mismatch repair deficiency causes colorectal cancers (CRCs) with microsatellite instability, which is, however, associated with relatively better survival rates. On the other hand, loss of *SMAD4*, a transcription factor in the TGF-β superfamily signaling, promotes tumor progression. Loss of heterozygosity on chromosome 18 can case SMAD4-deficient CRC, which results in poorer patients' survival. Such bidirectional phenomenon driven by TGF-β signaling insufficiency reflects the complexity of this signaling pathway in CRC. Moreover, recent understanding of CRC at the molecular level (consensus molecular subtype classification) provides deep insight into the important roles of TGF-β signaling in the tumor microenvironment. Here we focus on the TGF-β signaling in CRC and its interaction with the tumor microenvironment. We summarize the molecular mechanisms of CRC tumorigenesis and progression caused by disruption of TGF-β signaling by cancer epithelial cells and host stromal cells (Itatani Y, Kawada K, Sakai Y. Transforming Growth Factor-β Signaling pathway in colorectal cancer and its tumor microenvironment. *Int J Mol Sci*. 2019;20(23):5822).

STYLUS-BASED TACTILE PROFILOMETER CAN PRODUCE RELIABLE RESULTS OF GLASS IONOMERS' SURFACE ROUGHNESS MEASUREMENT: INTER- AND INTRA-OPERATOR RELIABILITY STUDY

STYLUS-BASED TACTILE PROFILOMETER CAN PRODUCE RELIABLE RESULTS OF GLASS IONOMERS' SURFACE ROUGHNESS MEASUREMENT: INTER- AND INTRA-OPERATOR RELIABILITY STUDY (Abstract): The roughness measuring instruments, which analyze the roughness degree of sample surface using a stylus, can give limited information about surface alterations. The alternative three-dimensional surface mapping methods have better performance, but their spread is limited. The aim of this study was to determine the intra- and inter-operator reliability of surface roughness measurements by three independent operators with a tactile stylus-based profilometer on glass ionomer specimens. **Material and methods:** Ten light-cured glass ionomer specimens, prepared according to the manufacturer's instructions from premeasured unit dose capsules of GC Fuji II LC CAPSULE, have been selected. Three previously trained operators measured individually in four diagonals the surface roughness of samples with MarSurf XR1 roughness measuring instrument. After ten days the measurements were repeated using the same protocol. The Average Roughness was used to characterize the surface texture. Intra-class correlation coefficients were calculated for both individual and group measurements to check the level of reliability of the used technique. **Results:** The inter- and intra-operator reliability of the measurements showed high degrees, the coefficient values being in the good (0.75-0.90) and excellent (>0.90) categories of reliability. **Conclusions:** Linear surface roughness measurements of dental materials using a tactile roughness measuring device can be performed with high reliability by single or multiple users. This procedure has its limitations and further studies, with more materials, are warranted in this topic. **Keywords:** GLASS IONOMER, SURFACE ROUGHNESS, PROFILOMETER, RELIABILITY.

There is a huge number of in vitro studies based on methodologies which uses different devices to measure microtopography on surfaces of dental materials and teeth. Among various available techniques, two different methods can be distinguished: the quantitative approach, based on surface profile analysis and the qualitative method, involving optical and scanning microscopy (1).

The profilometer uses a fixed stylus on an arm, which is constantly in contact with the surface, to show the micro-topography. As the tip of the stylus moves linear, the two-dimensional profile of surface is detected and a software allows computing different parameters of roughness profile and topography (2). The obtained results provide quantitative information about the linear route taken by the tip (3).

The non-contact approach is based on optical phenomena. The modern interferometers are applying white light to detect the roughness, in combination with microscopy (optical profilometer) a good resolution and significant vertical range can be obtained. Other optical devices used are: scanning confocal microscope, scanning electron microscope (SEM), scanning tunneling microscope (STM) and atomic force microscope (AFM) (2, 3).

In study designs based on repeated measurements of specimens, reliable roughness measurement protocols are necessary. A possible source of measurement errors arises from technical failure made by the same operator or multiple operators on the same specimen. The high degree of reliability, which refers to reproducibility and repeatability, is provided by identical or similar measurement results (4, 5).

The results of studies, aimed to quantify the accuracy of tactile profilometers are varied as are the used study designs and statistical methods, too (6-8). An eligible parameter of reliability is the intra-class correlation coefficient (ICC). ICC is designed to assess consistency or conformity between two or more quantitative measurements (9). This method is suitable to evaluate the inter- and intra-operator reliability of a procedure or a measurement (10). Reliability studies can be fully standardized only under laboratory conditions (11).

The aim of this study was to determine the intra- and inter-operator reliability of surface roughness measurements produced by three independent operators with a tactile profilometer on glass ionomer specimens. The null hypotheses tested were that the results obtained with the same methodology and repeated after 10 days, can produce high values (> 0.75) of both *i)* intra- and *ii)* inter-operator intra-class correlation coefficients.

MATERIAL AND METHODS

Ten resin reinforced glass ionomer specimens were prepared in accordance with the manufacturer's instructions by a single operator using GC Fuji II LC (GC EUROPE, Belgium) premeasured unit dose capsules. The standardized, uniform size of the disc-shaped samples were achieved by the use of a silicone mold having a plastic sheet attached at the bottom to obtain smooth surfaces. The activated and mixed capsules were dispensed with an applier into the 6 mm diagonal cavities of mold followed by 30 seconds of light curing with Demetron LC (Kerr Corporation, USA) halogen unit. The glass ionomer specimens were stored in distilled water between measurements.

Four diagonals of each specimen were measured using a calibrated contact profilometer (MarSurf XR1, Mahr Gmbh, Germany). After ten days the measurements were repeated. A diamond stylus traversed every diagonal in a length of 1,74 mm and with a cut-off length of 2,50 µm at a 0,10 mm/s speed (fig. 1). The cone shaped diamond tip with 90° angle had a radius of 2.00 µm. The used Average Roughness (R_a) surface texture parameter

represents the arithmetic average of all deviations of the profile from the centerline (12). The measuring process was performed by three different, previously trained operators. The operators worked alone at both measurements.

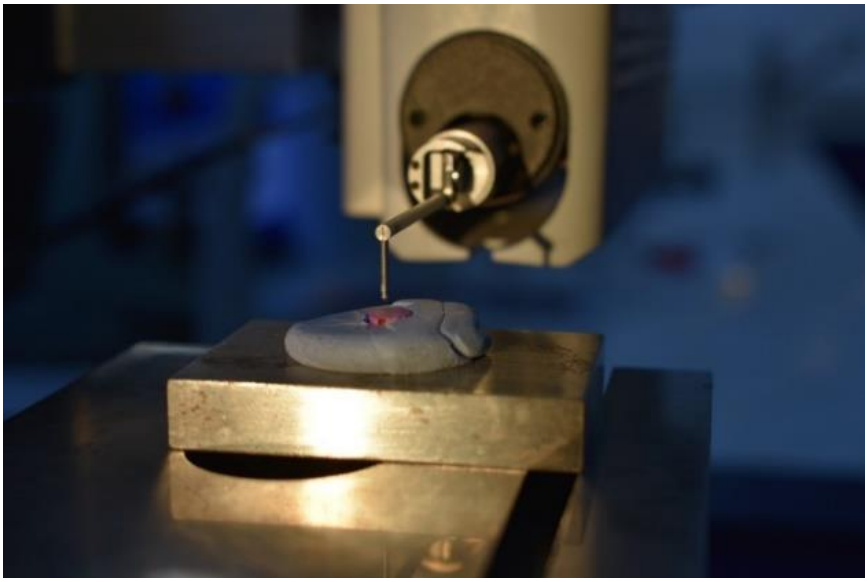

Fig. 1. The MarSurf XR1 computer-based tactile roughness measuring unit

The descriptive statistics, Kolmogorov-Smirnov normality test and data analysis were carried out using IBM SPSS Statistics a (IBM, USA). Intra-class correlation coefficients (ICC) and data distribution were calculated on 95% confidence interval for intra- and inter-operator measurements. The interpretation of results was based on the guideline given by Koo and Li (2016). According to them the values less than 0.5, between 0.5 and 0.75, between 0.75 and 0.9, and greater than 0.90 are indicative of poor, moderate, good, and excellent reliability (10).

RESULTS

A total number of 480 R_a values were measured by the three operators on both occasions. This number is the sum of the four diagonals measured twice on each specimen at both measurement periods by the three operators. The mean surface roughness values and standard deviations (SD) of specimens are shown in tab. I for every operator and measurement period. Data presented normal distribution.

The intraclass correlation coefficients from tab. II show high degrees of inter- and intra-operator reliability of the measurements, all values being higher than 0.75. The highest ICC values were found at the second inter-operator test containing overall measured values of the three operators (0.93) and at the intra-operator test of the first operator (0.90). Surface roughness measurements with the lowest ICC values were found at the first inter-operator test containing overall measurements of all operators (0.79) and at the second operator (0.78).

TABLE I

Mean R_a values of specimens' surface roughness at the two measurement periods

Measurement periods	Specimen	Operator 1 (Average ± SD)	Operator 2 (Average ± SD)	Operator 3 (Average ± SD)
First	S1	0.22 (± 0.07)	0.29 (± 0.10)	0.25 (± 0.06)
	S2	0.24 (± 0.06)	0.21 (± 0.01)	0.28 (± 0.11)
	S3	0.16 (± 0.02)	0.21 (± 0.10)	0.11 (± 0.05)
	S4	0.19 (± 0.07)	0.21 (± 0.03)	0.14 (± 0.01)
	S5	0.37 (± 0.07)	0.43 (± 0.05)	0.71 (± 0.24)
	S6	0.37 (± 0.02)	0.46 (± 0.06)	0.54 (± 0.33)
	S7	0.21 (± 0.03)	0.20 (± 0.06)	0.25 (± 0.09)
	S8	0.22 (± 0.05)	0.31(± 0.09)	0.65 (± 0.41)

	S7	0.16 (± 0.01)	0.15 (± 0.01)	0.23 (± 0.07)
	S8	0.24 (± 0.04)	0.29 (± 0.06)	0.35 (± 0.09)
	S9	0.16 (± 0.01)	0.15 (± 0.03)	0.28 (± 0.13)
	S10	0.25 (± 0.05)	0.25 (± 0.04)	0.31 (± 0.13)

TABLE II

Intraclass correlation coefficients according to inter- and intra-operator tests

	1st inter-operator (overall)	2nd inter-operator (overall)	1st vs. 2nd inter-operator (overall)	Intra-operator (Operator 1)	Intra-operator (Operator 2)	Intra-operator (Operator 3)
ICC	0.79	0.93	0.86	0.90	0.78	0.87

DISCUSSION

Reliability studies offer information about the reproducibility and repeatability of measurements made by a single operator or multiple operators (4). The necessity of this article is given by the lack of similar reliability studies in field of surface roughness of dental materials. Although, the obtained intra- and inter-operator results had a good and excellent reliability, it is visible that the repeatability of results are not perfect. The performance of operators may vary mildly (tab. II).

It does not exist a standard of minimal

procedures, measurements, samples, subjects, or operators to use for quality ICC estimates. Mehta *et al*. (2018) demonstrated that the increase of subjects in clinical studies beyond 80, does not have an impact on ICC (11). Contrary to clinical interventions, the in vitro research does not require patients' consent and does not raise ethical issues (13). In laboratory reliability studies the number of used samples is variable, frequently the sample size includes 10 specimens (14-16).

Studies found reliable the use of profilometer compared with other devices. Canabarro *et al*. (2009) found similar results of two- and three-dimensional profilometers in analysis of titanium surfaces (7). Other authors also highlighted the good performance of contact devices comparative with alternative methods, but they also recognize the disadvantages of this technology or suggest further examinations (6, 8, 17). The dimension of stylus defines the possible measurement errors. Authors found that the most accurate results are obtained using a 2 µm radius tip (18).

The tactile profilometers have several limitations. The speed of the tip across the surface was proved to be decisive in the success of results (19). If traversing speed of the stylus is too fast, an inaccurate tracking of surface profile may occur, inducing measurement errors (21). The constant contact of the specimen with the tip of the profilometer may cause surface damages, the resulting scratches being detrimental to the results or making the measurements non-repeatable (21). In these cases the incident is caused by the hardness of the analyzed materials and the diameter of the stylus (20). Heurich *et al*. (2009) demonstrated that the tip of the tactile profilometer penetrate the surface of preliminary eroded enamel causing scratches on the surface. Nevertheless, they found the unit suitable for analyzing eroded enamel if the appropriate testing force is being applied (22).

In contact profilometry the R_a value is a commonly used parameter. Although this parameter is easy to measure and it has a good reproducibility in repeated measurements, it gives limited information about the textural characteristics of a profile (12). This method provides quantitative information about heights at regular intervals. In some cases when the original profile of specimen has frequent amplitudes, the stylus sampled profile become distorted with broadened peaks and sharped valleys (23).

The optical devices can be an alternative to tactile measurement. In spite of all their advantages (non-contact working principle, high sensitivity, accuracy, and measurement speed), the physical properties of surfaces (reflectivity, elements which disturb the light path) sometimes influence the results. The results obtained with contact and non-contact methods cannot be always compared (2, 24).

CONCLUSSIONS

As all intra-class correlation coefficients calculated in this pilot study produced high values (>0.75), our null-hypotheses were confirmed. Linear surface roughness measurements of glass ionomer dental materials using a tactile roughness measuring device can be performed with high reliability by single or multiple users. Nevertheless, this device has its own limitations, which derive from its working principle and general characteristics. Further, larger scale studies including other materials are warranted in this topic.

DIGITAL TECHNOLOGY FOR REMOVABLE PARTIAL DENTURE REALIZATION. CASE REPORT (Abstract): The conventional fabrication of removable partial dentures is a complex process, which involves a lot of clinical and technological steps. The design of the elements must be performed in order to maintain the homeostasis and to rehabilitate, in optimal conditions, the functions of the stomatognathic system. Digital technology-Computer-aided design/computer-aided manufacturing (CAD/CAM) method for partial denture fabrication brings a lot of advantages: high accuracy of the denture, increases the strength and durability, avoid changes of the volume and, time working economy. This clinical report aims to illustrate the stages of getting a removable prosthesis, using the computerized method and to emphasize that digital prosthesis can be effective and accurate, eliminating or replacing steps that can lead to complications. **Keywords**: REMOVABLE PARTIAL DENTURE, CAD-CAM TECHNOLOGIES, METALLIC FRAMEWORK.

Removable partial denture is a device of great complexity, both in terms of choosing a correct design, adapted to the clinical situation, and in terms of effective technological execution. The elements of this removable prosthesis come in contact with the remaining teeth, but also with the oral mucosa and the bone support. In this case, the choice for the connector design and for the direct and indirect retainers will be made in order to restore homeostasis and the functions of the dento-maxillary system (1). An incorrectly made prosthesis will generate a series of pathological dental, periodontal, occlusal or physiognomic manifestations. The design of the removable prostheses must be realized according to the prosthetic area, not to overload the remaining teeth and the periodontium; thus, all functions altered by edentation will be rehabilitate in optimal conditions. The elaboration of a removable partial denture supposes a succession of clinical and technological steps; the rigorous observance of the steps and the knowledge of their particularities, as well as of the characteristics of the materials used will allow the realization of some prosthetic constructions with optimal resistance and with great clinical longevity. (2). The development of dental materials has diversified the technologies for prosthetic constructions, and knowing the particularities of each method, with their advantages, disadvantages, and limitations, allows choosing an appropriate therapeutic solution and solving the most diffi-

cult clinical situations, in optimal conditions. Modern digital technologies for prostheses realization are currently preferred, because they offer multiple advantages compared to classical methods: decreased number of appointments, high accuracy of the appliance, decreased duration of realization, superior quality control by clinicians and technician, possibility to change the design and to remanufacture without the need to restart the entire process; also, digital solutions allow the application of advanced materials, reduce material costs and casting equipment, so it will allow less wasted alloy, no wasted wax and no wasted investment material (3, 4). The development of the precise design procedures, including computer-aided design and manufacturing CAD/CAM, for fabrication partial dentures is justified because there is still a large group of patients who would benefit on improving the accuracy of these solutions (5, 6).

CASE REPORT

Patient S.O., 59-year-old came to the dentist's office with functional disorders caused by the loss of several masticatory units, both on the maxillary and on the mandible (fig. 1).

Fig. 1. Clinical examination

After performing the clinical and the paraclinical examinations (orthopantomography and model study) the diagnostic was of partial maxillary and mandibular edentation; as a therapeutic solution was chosen, for the maxilla a removable partial denture, with two saddles, reduced palatal plate as main connector and encircling clasps, as elements of retention, support, and stabilization. For the mandible, a removable partial denture was indicated: with two saddles, a lingual bar as connector and also clasps, for the retention

The process for fabricating removable partial dentures has three major steps: the impression procedures, the denture design, and the denture fabrication. The first step consisted into an optical impression of the maxillary and mandibular prosthetic area and occlusal contacts in maximum intercuspal registration (fig. 2).

To realize the prosthetic device, we used the DIGISTELL system, 3D CAD software for removable partial frameworks. The data were sent to the CAD- CAM work unit and, based on the recorded images, the CAD component will analyze the prosthetic area and provide indications which teeth will be applied the clasps, the dental areas to be prepared for the application of the occlusal rests and the teeth for possible coronoplasty; it will also propose a design for the future

prosthesis, indicating the types of connector, the most appropriate clasps for the clinical situation, as well as the relationship with the abutment teeth (fig. 3).

Fig. 2. Optical impression

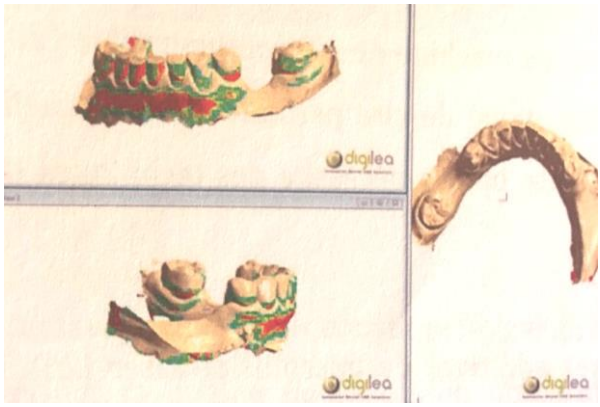

Fig. 3. The design of the future framework

The doctor will make the preparations on the support teeth, will prepare the organic substructure, in order to apply a crown on 2.5 premolar. Then, a new optical impression is registered, with the prosthetic area prepared for the device.

Based on the second impression, virtual models will be developed, corresponding to the new clinical situation, on which virtual frameworks of the future prosthesis will be created (fig. 4).

After establishing the design of the partial removable dentures, the information was transmitted to the CAM unit where the

actual milling of the metal infrastructures is done, using chromium-cobalt-tungsten-based alloy blocks. The framework was checked in the oral cavity, then the dental technician, in the laboratory, made the acrylic component of the saddles and the mounting of artificial teeth. After processing and finishing the prostheses, they are sent to the dental office for verification and intraoral adaptation (fig. 5).

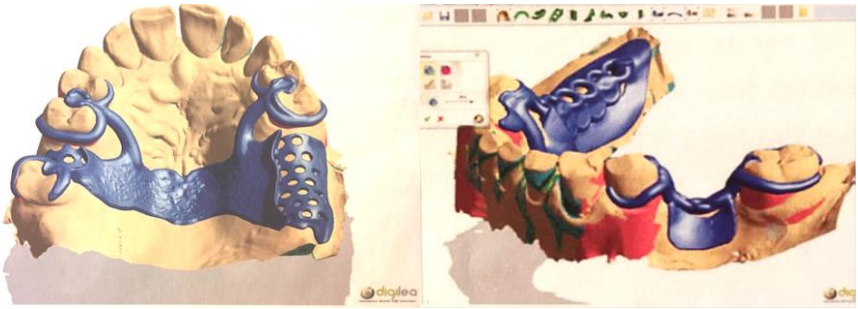

Fig. 4. The models and the wax-up of the frameworks

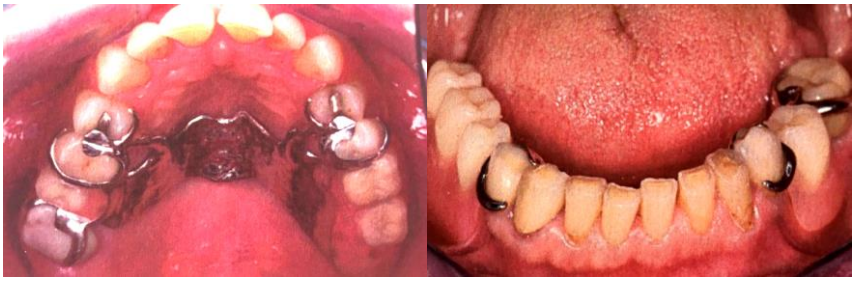

Fig. 5. Intraoral adaptation

DISCUSSION

Making removable partial dentures using CAD-CAM methods has many advantages recording with high precision all the details of the prosthetic area due to the optical impression, designing the framework on a virtual model and analyzing the therapeutic possibility depending on clinical situations, material economy, as a result of eliminating laboratory steps, high accuracy in realizing each element of the prosthesis (7, 8, 9).

For a correct adaptation of the prosthesis, the relationship between elements of retention, support and stabilization and abutment teeth is extremely important. In general, bone resorption at the level of edentulous ridges is asymmetric, which determines an uneven distribution of pressures; therefore, any deviation, even a minor one, of the metal framework geometry can lead to a destabilization of the prosthesis (10, 11).

Computerized technologies eliminate the risk of errors in the design and execution of removable partial dentures, allowing the realization of high-precision prosthetic constructions, correctly adapted and with great longevity over time.

CONCLUSIONS

The individualized treatment of the par-

tial edentation requires an in-depth knowledge of the clinical situation and of the elements of the edentulous prosthetic area, in order to adapt the therapeutic possibilities to the clinical particularities, so as to ensure an optimal morpho-functional rehabilitation. The multitude of prosthetic technologies and the diversification of materials over time, on the one hand make it difficult for the doctor and dental technician to provide the choice of the best solution and, on the other hand, offer a wide range of technological possibilities, allowing individualization of the treatment plan.

Nowadays, there are a large number of devices, technologies and materials that are available to the doctor, but especially to the technician for the realization of removable partial prostheses that correspond to the mechanical, biological, and prophylactic desideratum.

The development of the precise design procedures, including computer-aided design and manufacturing CAD/CAM, for fabrication of partial dentures is justified by many advantages compared to the classical methods.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest and they received no specific funding regarding this scientific research.

SEA BUCKTHORN FRUIT OIL SUPPLEMENTATION IN ACTIVE RHEUMATOID ARTHRITIS: A FOCUS ON COMPOSITE DISEASE ACTIVITY INDICES AND EULAR RESPONSE (Abstract): Rheumatoid arthritis is a disabling disease whose treatment options have limitations with regard to efficacy and safety. In this respect, combination of conventional treatment with plant-derived products has attracted considerable interest in recent years. The aim of this study was to assess the impact of sea buckthorn fruit oil supplementation in patients with active rheumatoid arthritis. **Materials and methods:** Eighty patients, diagnosed with active rheumatoid arthritis and treated with a combination of methotrexate (15 mg/week) and diclofenac sodium (50 mg/day), were randomly (1:1) divided into control and experimental groups, the latter being supplemented with sea buckthorn fruit oil (1800 mg/day). The study lasted 12 weeks. The benefits of sea buckthorn fruit oil supplementation were evaluated by various composite disease activity indices (disease activity score in 28 joints, DAS28; simplified disease activity index, SDAI; clinical disease activity index, CDAI) and European League Against Rheumatism (EULAR) response. **Results:** Twelve-week supplementation with sea buckthorn fruit oil significantly ($p< 0.001$) reduced composite disease activity indices in comparison with baseline and control. At week 12, patients in the experimental group showed higher rates of good and moderate EULAR responses than those in the control group. **Conclusions:** According to our results, sea buckthorn fruit oil is a promising option for the adjunctive treatment in rheumatoid arthritis. **Keywords:** SEA BUCKTHORN FRUIT OIL, ACTIVE RHEUMATOID ARTHRITIS, COMPOSITE DISEASE ACTIVITY INDEX, EULAR RESPONSE.

INTRODUCTION

Rheumatoid arthritis (RA) is a chronic systemic autoimmune-inflammatory disease characterized by articular and extraarticular manifestations (synovial membrane inflammation, articular cartilage destruc-

tion, periarticular bone erosion and subcutaneous nodules, lung disease, pericarditis, respectively). If inadequately treated, it results in permanent joint deformities, functional disability and poor life quality (1, 2). The drugs used to treat RA, specifically corticosteroids, nonsteroidal anti-inflammatory drugs (NSAIDs), conventional and biological disease-modifying antirheumatic drugs (DMARDs), produce severe side effects. In addition, none of these drugs, alone or in combination, induce a medication-free remission. For this reason, supplementation with plant-derived products to support the efficacy and safety of conventional treatment has attracted considerable interest in recent years (1).

The benefits of coadministration of herbal extracts/phytochemicals with antiarthritic drugs were demonstrated in clinical studies. In RA patients, *Tripterygium wilfordii* Hook.f. extracts improved the therapeutic efficacy of methotrexate (MTX) as evaluated by clinical outcomes and reduction in inflammatory and diagnostic markers (erythrocyte sedimentation rate (ESR), C reactive protein (CRP) and rheumatoid factor (RF), respectively). Supplementation with total glucosides of peony (*Paeonia lactiflora* Pall.) in RA patients, treated with MTX or MTX in combination with leflunomide, reduced liver toxicity caused by DMARDs, ameliorated clinical symptoms, ESR, CRP, RF and lipid profile (3). The combination of dry olive (*Olea europaea* L.) leaf extract with MTX was more efficient than MTX alone in restoring antioxidant defense and reducing oxidative stress, cell damage and interleukin-6 (IL-6) production in early phase RA patients (4). Supplementation with garlic (*Allium sativum* L.) powder in patients with moderate to severe RA, under treatment with DMARDs, resulted in improved clinical symptoms and significant reductions in CRP and tumor necrosis factor- α (TNF-α) compared to patients receiving only DMARDs (5). Also, combinations of pure phytochemicals with antiarthritic drugs were reported to exert better activity and less toxicity than antiarthritic drugs alone. Combined administration of resveratrol with conventional DMARDs induced greater improvement in clinical, biochemical (RF, ESR, CRP, TNF-α, IL-6) and hip fracture (undercarboxylated osteocalcin) markers (6). Sesamin supplementation attenuated pain intensity and significantly decreased CRP, TNF-α, cyclooxygenase-2 (COX-2), hyaluronidase and matrix metalloproteinase-3 (MMP-3)(7). In RA patients, the therapeutic efficacy of sinomenine in combination with MTX was comparable with that of MTX-leflunomide combination but the safety and tolerability (with respect to gastrointestinal and hepatic side effects) were better (8). The combination of curcumin with diclofenac sodium (DicNa) induced better clinical outcomes in comparison with DicNa in patients with active RA (9).

Due to a unique mixture of bioactive compounds, sea buckthorn (*Elaeagnus rhamnoides* (L.) A. Nelson syn. *Hippophae rhamnoides* L., Elaeagnaceae) fruit oil is one of the most valuable plant-derived products. The oil obtained from whole berries is rich in palmitoleic acid (11-37%), an ω-7 fatty acid, other unsaturated fatty acids such as ω-3, ω-6 and ω-9 fatty acids (3-8% α-linolenic acid, 12-18% linoleic acid and 20-53% oleic acid, respectively) and saturated fatty acids (23-40% palmitic acid, < 2% stearic acid), sterols (1200-2300 mg/100 g), carotenoids (350-520 mg/100 g) and tocopherols (up to 160 mg%, α-tocopherol being predominant) (10, 11). Sea buckthorn fruit oil has applications in skin and mucosal disorders (wounds, burns, lesions caused by radiation exposure, hyper pigmentation, infections, itchiness, vaginal

inflammatory atrophy). As nutraceutical, sea buckthorn fruit oil has benefits in the prevention and adjunctive treatment of cardiovascular, liver and metabolic diseases. In cancer patients undergoing chemotherapy and radiotherapy, sea buckthorn fruit oil counteracts some of treatment side effects such as alterations in liver and kidney function and appetite loss (10-12).

The current study was designed to evaluate the efficacy and safety of sea buckthorn fruit oil (SBFO) supplementation in patients with active RA. Disease activity score in 28 joints (DAS28), simplified disease activity index (SDAI), clinical disease activity index (CDAI)and European League Against Rheumatism (EULAR)response were used as efficacy indicators.

MATERIALS AND METHODS

A pilot randomized controlled study was conducted in accordance with the Declaration of Helsinki. The study was approved by the Institutional Ethics Committee of *Grigore T. Popa* University of Medicine and Pharmacy Iasi, Romania (approval no. 68/13.04.2021) and Ethics Committee of the Clinical Rehabilitation Hospital Iasi, Romania (approval no. 13/20.04.2021).All enrolled patients filled in and signed the written informed consent. In brief, 80 patients diagnosed with active RA were randomly classified (1:1) into two groups: control group, treated with MTX (15 mg/week) and DicNa (50 mg/day) and experimental group, receiving the aforementioned medication and SBFO (1800 mg/day, Sea Buckthorn Oil 900 mg, S.C. Hofigal Export Import S.A., Bucharest, Romania). The study lasted 12 weeks. The inclusion and exclusion criteria and baseline characteristics of patients were described in detail elsewhere (Zugravu *et al.*, submitted).

The inflammatory markers (ESR, CRP),lipid profile, glycemia, liver and renal function markers were assessed at baseline and week 12. Venous blood (10 mL) was collected after fasting (10-12 h). A volume of 2 mL was used for ESR measurement (Westergren method, THERMA analyzer, Linear Chemicals, Montgat-Barcelona, Spain). The remaining volume was centrifuged (3000 g, 10 min.) to separate serum and plasma which were further stored at -80°C. Serum CRP was determined by immunoturbidimetry (biochemical analyzer XL 1000, Erba, Lachema S.R.O., Czech Republic). Liver and kidney function markers, lipid and carbohydrate metabolic markers were determined spectrophotometrically (biochemical analyzer XL 1000, Erba, Lachema S.R.O., Czech Republic).

The clinical variables, assessed at baseline and week 12, were the tender joint count (in 28 and 68 joints, TJC28 and TJC68), swollen joint count (in 28 and 66 joints, SJC28 and SJC66) and morning stiffness (in min.) (13, 14). Composite disease activity indices such as DAS28 (15), SDAI andCDAI (13) were also evaluated at the beginning and end of the study. EULAR responses were assessed at week 12 according to improve mentin DAS28 score (15). DAS28, SDAI, CDAIand EULAR responses were calculated as previously reported (13, 15).

Data were analyzed using the SPSS software (version 25). The Kolmogorov-Smirnov test was initially used to assess the normality of data distribution. The differences between the two groups (experimental and control groups) at each evaluation (baseline and week 12) and the differences between the evaluations for each group were examined using either parametric or nonparametric tests. The independent samples *t*-test and Mann-Whitney test were used to compare the differences between experimental and control groups. Within

each group, the comparisons were done using the paired samples *t*-test (normally distributed data) and Wilcoxon signed-rank test (non-normally distributed data). The Chi-square test was applied to assess the relationship between two qualitative variables and two patient groups. Values of *p* less than or equal to 0.05 were considered statistically significant.

RESULTS

The inflammatory markers (ESR, CRP) were not significantly ($p > 0.05$)different between the two patient groups at baseline and week 12. At week 12, CRP decreased in both experimental and control groups; ESR had slightly reduced values in the control group and unexpectedly higher values in the experimental group (tab. I).

TABLE I.
Inflammatory markers at baseline and week 12

Inflammatory marker	Control group	Experimental group	*p* value
ESR (mm/h)			
Baseline	29.57 ± 22.74	27.12 ± 20.59	0.615[a]
(95% CI)	(22.30 – 36.84)	(20.53 – 33.71)	
Week 12	28.38 ± 23.61	32.10 ± 26.46	0.519[a]
(95% CI)	(20.73 – 36.03)	(23.28 – 40.93)	
Change	1.02 ± 12.43	-4.21 ± 20.96	-
p value	0.609[b]	0.229[b]	-
CRP (mg/dL)			
Baseline	17.50 ± 29.95	9.44 ± 19.37	0.158[a]
(95% CI)	(7.92 – 27.08)	(3.25 – 15.64)	
Week 12	14.08 ± 34.44	7.51 ± 9.51	0.258[a]
(95% CI)	(2.92 – 25.25)	(4.34 – 10.68)	
Change	3.81 ± 17.32	2.43 ± 14.18	-
p value	0.177[b]	0.303[b]	-

Values are expressed as mean ± standard deviation for normally distributed variables and median (25th and 75th percentiles) for non-normally distributed variables and 95% confidence interval; ESR, erythrocyte sedimentation rate; CRP, C reactive protein; [a] Independent t test; [b] Paired t test.

At baseline, there were no significant ($p > 0.05$) differences between the two groups with respect to the clinical variables (TJC28, TJC68, SJC28, SJC66, morning stiffness) and composite indices of disease activity such as DAS28 calculated with ESR or CRP (DAS28 (ESR) and DAS28 (CRP), respectively), SDAI and CDAI. In the experimental group, supplementation with SBFO for 12 weeks markedly ($p< 0.001$) improved all clinical variables and indices with significant differences between the values at baseline and week 12. At week 12, all clinical variables were significantly ($p< 0.001$) different between the experimental and control groups. On the other hand, at the end of the study, in the control group, the scores of clinical variables (except TJC28 and morning stiffness) significantly ($p \leq 0.001$) increased indicating higher disease activity and deterioration of patient condition (tab. II).

TABLE II.
Clinical variables at baseline and week 12

Outcome	Control group	Experimental group	*p* value
TJC28			
Baseline	19.72 ± 3.88	18.65 ± 4.58	0.261[a]
(95% CI)	(18.48 – 20.96)	(17.18 – 20.11)	
Week 12	20.43 ± 3.44	12.21 ± 2.83	< 0.001[a]
(95% CI)	(19.31 – 21.55)	(11.26 – 13.16)

Morning stiffness (min.)			
Baseline	40.12 ± 22.68	40.12 ± 18.30	1.000[a]
(95% CI)	(32.86 – 47.38)	(34.26 – 45.98)	
Week 12	45.12 ± 16.28	21.62 ± 7.64	< 0.001[a]
(95% CI)	(39.85 – 50.41)	(19.07 – 24.16)	
Change	-4.74 ± 16.73	19.45 ± 18.17	-
p value	0.084[b]	< 0.001[b]	-

Values are expressed as mean ± standard deviation for normally distributed variables and median (25th and 75th percentiles) for non-normally distributed variables and 95% confidence interval (CI); TJC28, tender joint count in 28 joints; TJC68, tender joint count in 68 joints; SJC28, swollen joint count in 28 joints; SJC66, swollen joint count in 66 joints; a Independent t test; b Paired t test.

The composite indicesDAS28 (ESR), DAS28 (CRP), SDAI and CDAI were used to assess disease activity. DAS28 > 5.1, 3.2 < DAS28 ≤ 5.1 and DAS28 ≤ 3.2 indicate high, moderate and low disease activity, respectively; DAS28 less than 2.6 is an indicative of remission. SDAI > 26, 11 < SDAI ≤ 26 and 3.3 < SDAI ≤ 11 define high, moderate and low activity, respectively whereas SDAI ≤ 3.3 indicates remission. CDAI > 22, 10 < CDAI ≤ 22, 2.8 < CDAI ≤ 10 and CDAI ≤ 2.8 correspond to high, moderate, low activity and remission, respectively (13). According to the mean values of these composite indices, patients in both groups had high disease activity at baseline (DAS28 (ESR)/(CRP) > 5.1, SDAI > 26, CDAI > 22). At week 12, in the control group, patients still had high disease activity whereas in the experimental group, patients achieved moderate disease activity according to DAS28 (CRP) and SDAI (4.66 ± 0.58 and 25.13 ± 6.70, respectively). However, it is worthy to note that supplementation with SBFO induced significant (p< 0.001) reductions in DAS28 (ESR)/(CRP), SDAI and CDAI compared to baseline and control (tab.III). As shown in fig. 1-3, at baseline, 87.2-97.4% patients in the control group and 89.2-100% patients in the experimental group had high disease activity according to DAS28 (ESR)/DAS28 (CRP)/SDAI/CDAI scores. At week 12, the percentage of patients with high disease activity increased in the control group (from 94.9 to 100% according to DAS28 (ESR), from 87.2 to 97.4% according to DAS28 (CRP), from 97.4 to 100% according to SDAI and CDAI). In the experimental group, 12-week supplementation with SBFO resulted in a marked decline in patients presenting high disease activity (from 97.3 to 64.9% according to DAS28 (ESR), from 89.2 to 13.5% according to DAS28 (CRP), from 94.6 to 48.6% according to SDAI, from 100 to 64.9% according to CDAI) with a concomitant elevation in patients with moderate disease activity (from 2.7 to 35.1% according to DAS28 (ESR), from 10.8 to 86.5% according to DAS28 (CRP), from 5.4 to 51.4% according to SDAI, from 0 to 35.1% according to CDAI).

After 12-week supplementation, SBFO significantly (p< 0.001) improved EULAR-responses calculated with ESR or CRP (EULAR (ESR) and EULAR (CRP), respectively).Thus, in the experimental group, patients attained good and moderate EULAR responses in high rates (EULAR (ESR) good response: 35.1% *vs.* 0% in the control group, EULAR (CRP) good response: 59.5% *vs.* 0% in the control group, EULAR (ESR) moderate response: 56.8% *vs.* 2.6% in the control group, EULAR (CRP) moderate response: 40.5% *vs.* 0% in the control group) (fig.4). Most of the clinical laboratory parameters were not significantly different between the experimental and control groups at the beginning and end of the study. After 12-week supplementation, SBFO reduced total cholesterol (TC) and low-density lipoprotein cholesterol (LDL-C) and increased triglycerides (TG) but the differences compared to baseline and control were not significant (p > 0.05). Surprisingly, SBFO caused a significant (p< 0.001) reduction in high-density lipoprotein cholesterol (HDL-C). SBFO improved liver function as evaluated by aspartate aminotransferase (AST), alanine aminotransferase (ALT) and gamma-glutamyl transferase (GGT) levels. At week 12, in the experimental group, all three enzymes showed lower levels compared to baseline (p > 0.05) whereas higher levels compared to baseline were detected in the control group (p > 0.05). SBFO supplemen-

tation significantly ($p< 0.05$) decreased ALT compared to control. SBFO supplementation also reduced serum levels of urea and uric acid and had little impact on creatinine ($p > 0.05$ compared to baseline). At week 12, urea and creatinine levels were significantly ($p = 0.001$) lower in the experimental group compared to control. A nonsignificant ($p > 0.05$) increase in glycemia and serum alkaline phosphatase (ALP), marker of liver damage, was detected in the experimental group at week 12 (tab. IV). A single adverse event was reported during the study period: one patient in the control group suffered from nausea after MTX administration.

TABLE III.
Composite indices at baseline and week 12

Outcome	Control group	Experimental group	*p* value
DAS28 (ESR)			
Baseline	6.50 ± 0.71	6.34 ± 0.69	0.292[a]
(95% CI)	(6.27 – 6.73)	(6.11 – 6.56)	
Week 12	6.68 ± 0.71	5.31 ± 0.64	< 0.001[a]

Values are expressed as mean ± standard deviation for normally distributed variables and median (25th and 75th percentiles) for non-normally distributed variables and 95% confidence interval (CI); TC, total cholesterol; HDL-C, high-density lipoprotein cholesterol; LDL-C, low-density lipoprotein cholesterol; TG, triglycerides; GL, glycemia; ALT, alanine aminotransferase; AST, aspartate aminotransferase; GGT, gamma-glutamyl transferase; ALP, alkaline phosphatase; an Independent t test; b Paired t test.

DISCUSSION

According to the clinical variables (TJC28, TJC68, SJC28, SJC66, morning stiffness) and efficacy indicators (DAS28 (ESR)/(CRP), SDAI, CDAI, EULAR(ESR) / (CRP)response), supplementation with SBFO significantly alleviated joint pain, swelling, physical disability and stiffness in RA patients.

ESR and CRP are frequently used to detect and monitor systemic inflammation in routine clinical practice. CRP is a better marker of systemic inflammation compared to ESR. CRP is primarily produced in hepatocytes in response to proinflammatory cytokines (IL-6) whereas ESR is an indica-

tor of plasma level of acute phase proteins (16). At week 12, in SBFO group, CRP decreased while ESR increased compared to baseline values. This discrepancy might result from the fact that, in contrast to CRP, ESR level is also affected by factors that are not associated with chronic inflammation such as age, gender, body mass index, physical activity, common metabolic abnormalities, smoking and alcohol consumption (17).Our results are in agreement with previous clinical investigations reporting little impact of sea buckthorn fruit oil on CRP level. In a double-blinded, randomized, placebo-controlled crossover study (2 × 8 weeks, 4-week washout), sea buckthorn fruit oil supplementation (2000 mg/day) did not induce significant changes in plasma levels of CRP and other markers of inflammation (antitrypsin, orosomucoid, leukocytes). Sea buckthorn fruit oil was a commercially available product obtained from fruit flesh and seeds by supercritical carbon dioxide extraction (18). In obese children, sea buckthorn pulp oil (800 mg/day for 60 days) had weak effect on CRP (19).

In our study, SBFO supplementation (1800 mg daily, 12 weeks) did not significantly influence the lipid profile except HDL-C; the latter significantly decreased in SBFO group at week 12. The decrease in HDL-C in SBFO group was unexpected and might be attributed to the antihypertensive medications used by patients. Thus, 32.4% of patients in the experimental group were under treatment with nonselective β blockers for hypertension in comparison to only 5.1% of patients in the control group. The aforementioned medication has been reported to negatively impact the lipid profile by decreasing HDL-C and increasing TG (20-22). Previous studies investigating the impact of sea buckthorn oil on lipid profile reported inconsistent results. In mice fed a high-fat diet, sea buckthorn pulp oil lowered TG (serum, hepatic), TC (serum), LDL-C (serum, hepatic) but also HDL-C (serum, hepatic) (23). In healthy normolipidemic subjects, administration of sea buckthorn fruit oil obtained by supercritical carbon dioxide extraction (5 g/day, 4 weeks, crossover study) caused no change in plasma lipids (24). In obese children, sea buckthorn pulp oil (800 mg/day, 60 days) significantly improved plasma TC and TG but had weak effect on LDL-C and HDL-C levels (19). A significant increase in HDL-C was detected in atopic dermatitis patients supplemented with sea buckthorn pulp oil (5 g/day, 4 months) (25).

In the present study, at week 12, liver markers (AST, ALT, γ-GT) showed lower levels in SBFO group compared to control, with a significant reduction for ALT.Regarding other biochemical parameters, 12-week supplementation with SBFO (1800 mg daily) did not have a significant impact on ALP, GL, urea, creatinine and uric acid levels. Overall, SBFO was well-tolerated in patients with active RA.

CONCLUSIONS

The present study indicates beneficial effects of SBFO supplementation in active RA with significant improvements in composite disease activity indices and EULAR response. Taking into account boththe efficacy and safety of SBFO, the latter seems to be a promising option for the adjunctive treatment in RA. However, the impact of SBFO supplementation on

various inflammatory and oxidative stress markers needs to be further investigated. Different doses of SBFO should also be evaluated to determine the optimal dosage for the best therapeutic outcome.

IMPACT OF TREATMENT ON QUALITY OF LIFE IN PATIENTS DIAGNOSED WITH POTENTIALLY MALIGNANT ORAL DISEASES (Abstract): This study **aimed** to investigate the impact of treatment on the quality of life (QoL) in patients diagnosed and treated for potentially malignant oral diseases (OPMDs) such as leukoplakia, oral lichen planus, and actinic cheilitis. OPMDs are chronic diseases with a significant risk of cancerous transformation, affecting 1% to 5% of the global population. Symptoms like pain, burning sensation, trismus, and altered taste adversely affect patients' QoL, compounded by delays in diagnosis. **Materials and methods:** This cross-sectional study, conducted from June 2023 to June 2024, involved 30 patients from the "Sf. Spiridon" Emergency Clinical Hospital in Iasi, Romania. Participants were assessed using a disease-specific QoL questionnaire, which included 20 questions across four subscales: difficulty with diagnosis, physical and functional limitations, psychological and social well-being, and the effect of treatment on daily life. **Results:** Participants consisted of 16 males (53.3%) and 14 females (46.7%), aged between 42 and 75 years, with an average age of 64.61±13.69 years. Patients with oral lichen planus and leukoplakia had a statistically significantly lower quality of life compared to patients with actinic cheilitis ($p = 0.038$). **Conclusions:** The three groups indicated a varied impact of the diseases and treatments on different aspects of life. Implementing disease-specific QoL assessment tools can aid in better understanding and addressing the special needs of OPMD patients, ultimately improving treatment outcomes and patient care. **Keywords:** POTENTIALLY MALIGNANT ORAL LESIONS, LEUKOPLAKIA, ORAL LICHEN PLANUS, ACTINIC CHEILITIS, QUALITY OF LIFE.

The World Health Organization (WHO) defines quality of life as the way a person perceives their position in life, considering the culture, the value system in which they live, as well as their goals, expectations, standards, and concerns. The need to correlate the perception of health with the ability to carry out daily activities led to the formulation of the concept of health-related quality of life. It includes self-perception as a crucial aspect of health assessment and helps to understand the impact of disease on individuals' social lives (1).

Potentially malignant oral diseases

(OPMDs) enhance morbidity and mortality due to the risk of neoplastic transformation (2, 3). Globally, OPMDs (leukoplakia, erythroplakia, oral lichen planus, oral submucosal fibrosis, actinic cheilitis) are reported to affect between 1% and 5% of the population (4). Careful monitoring of these lesions by an experienced specialist is crucial to detect malignant changes in the early stages, thus helping to reduce the incidence of cancer. Patients with OPMDs present with severe symptoms that influence quality of life (QoL). The common symptoms of OPMDs, such as pain, burning sensation, trismus, and altered taste, together with delays in diagnosis, lead to a clear deterioration in the quality of life of patients (5-10).

Patients' perceptions of quality of life are usually measured by questionnaires, which may be general or disease-specific. However, existing general questionnaires do not address these specific issues. A quality of life questionnaire designed for a specific disease is valuable for detecting changes over time, including responses to treatment. The Oral Health Impact Profile (OHIP), Oral Health Quality of Life (OHQL), and Chronic Oral Mucosal Disease Questionnaire (COMDQ) have been utilised in OPMD investigations (11-13).

This study aimed to support ongoing efforts to improve patients' experiences by providing a detailed and comparative assessment of quality of life for patients with OPMD after treatment, using the spicific OPMDQoL questionnaire.

MATERIALS AND METHODS

Research design

The present cross-sectional study was conducted between June 2023 and June 2024 among patients diagnosed and treated for potentially malignant oral lesions. Prior to the initiation of the study, approval was obtained from the research ethics committee of the "Grigore T. Popa" University of Medicine and Pharmacy in Iasi (No. 320/5.06.2023) and the "Sf. Spiridon" County Clinical Emergency Hospital in Iasi, Romania (No. 35/24.04.2023).

Study group

The study included 30 patients under observation who were diagnosed and treated for oral leukoplakia (OL), oral lichen planus (OLP), and actinic cheilitis (AC) in the Department of Oral and Maxillofacial Surgery (OMF) at the "Sf. Spiridon" Emergency Clinical Hospital in Iasi, Romania.

The inclusion criteria for participation in the study were voluntary participation, full completion of the questionnaires, and diagnosis of leukoplakia, oral lichen planus, or actinic cheilitis, while the exclusion criteria were diagnosis of other potentially malignant oral diseases or confirmation of malignancy in lesions through histopathological examination.

The objectives and procedures of the study were explained to the patients, and informed consent was obtained for completing the questionnaire, ensuring the anonymity and confidentiality of the answers, as well as the voluntary nature of participation. Patients received detailed instructions before starting the questionnaire, and any misunderstandings were clarified by the investigators, ensuring full completion of the questionnaires.

Study instrument

The OPMDQoL questionnaire (14) is designed to capture patients' views on how these conditions impact their daily lives. It includes 20 questions divided into four subscales that assess their life and activities after treatment: challenges with the diagnosis, physical and functional limitations,

psychological and social well-being, and the impact of treatment on daily life. Each question uses a five-point Likert scale: 0 for not at all, 1 for a little bit, 2 for somewhat, 3 for quite a bit, and 4 for very much. The total possible score ranges from 0 to 80, with higher scores indicating a lower quality of life.

The Romanian version of the QoL questionnaire for OPMD patients used in this study demonstrated strong internal consistency, with Cronbach's alpha coefficients as follows: 0.768 for difficulty with the diagnosis, 0.813 for physical and functional limitations, 0.887 for psychological and social well-being, and 0.811 for the effect of treatment on daily life.

Statistical analysis

The descriptive statistical analysis was performed using IBM *Statistical Package for the Social Sciences (SPSS) software version 26.0*. Differences between groups were determined using the Chi-square and ANOVA tests. A significance level of p-value<0.05 was considered.

RESULTS

Study group

The study group included 30 patients with OPMD, treated surgically or with medication, of which 14 were female (46.7%) and 16 were male (53.3%), aged between 42 and 75 years and an average age of 64.61±13.69 years. Most patients (16, 53.3%) came from the urban environment. Most patients (16, 53.3%) had completed high school, and very few had higher education (3, 10%). Participants' characteristics are presented in first table.

The responses given by the study participants to the first questionnaire subscale are presented in second table.

TABLE I.

Characteristics of study participants (N=30)

	Participants	Frequency N	Percent %
Variables	**Gender**		
	Male	16	53.3
	Female	14	46.7
	Age (mean ± SD [1])	64.61±13.69	
	≤ 50 years	8	26.7
	> 50 years	22	73.3
	Environment		
	Urban	16	53.3
	Rural	14	46.7
	Educational level		
	Secondary school	11	36.7
	High school	16	53.3
	Higher education	3	10

[1] SD standard deviation

TABLE II.
Patients' responses to the first subscale, Difficulties with Diagnosis

Difficulties with diagnosis	Leukoplakia (n=10)	Oral lichen planus (n=10)	Actinic cheilitis (n=10)	Total	*p*-value
	N (%)	N (%)	N (%)		
Q1. How difficult was it for you to get your mouth condition diagnosed?					
Not at all	2 (20%)	0 (0%)	4 (40%)	6 (20%)	
A little bit	3 (30%)	1 (10%)	2 (20%)	6 (20%)	
Somewhat	3 (30%)	2 (20%)	4 (40%)	9 (30%)	*0.047* *
Quite a bit	2 (20%)	4 (40%)	0 (0%)	6 (20%)	
Very much	0 (0%)	3 (30%)	0 (0%)	3 (10%)	
Q2. How much did the need to visit many doctors for getting your mouth condition diagnosed affect daily life activities?					
Not at all	2 (20%)	1 (10%)	1 (10%)	4 (13.33%)	
A little bit	1 (10%)	1 (10%)	3 (30%)	5 (16.66%)	
Somewhat	3 (30%)	3 (30%)	2 (20%)	8 (26.66%)	0.898
Quite a bit	2 (20%)	4 (40%)	3 (30%)	9 (30%)	
Very much	2 (20%)	1 (10%)	1 (10%)	4 (13.33%)	
Q3. How stressful was it for you to take a variety of treatments before being diagnosed with your mouth condition?					
Not at all	1 (10%)	1 (10%)	1 (10%)	3 (10%)	
A little bit	3 (30%)	1 (10%)	2 (20%)	6 (20%)	
Somewhat	2 (20%)	2 (20%)	3 (30%)	7 (23.33%)	0.854
Quite a bit	1 (10%)	4 (40%)	3 (30%)	8 (26.66%)	
Very much	3 (30%)	2 (20%)	1 (10%)	6 (20%)	
*Significance level of 0.05 (Chi-square test)					

The first question (Q1) indicated that 30% (n=9) of OPMD patients had slight difficulty getting their mouth condition diagnosed. Patients with OLP faced notably more challenges in obtaining a clear diagnosis compared to those with other OPMDs (p=0.047). Because the patients consulted multiple doctors for their diagnosis (Q2), 26.66% reported that this somewhat impacted their daily activities, while 13.33% indicated it had a significant impact. Most patients experienced some stress (Q3) while undergoing various treatments before their diagnosis, although 10% reported not being stressed.

Table III presents the responses given by the study participants to the second questionnaire subscale.

The assessment of patients' physical and functional limitations (tab. III) revealed that 9 patients (30%) experienced moderate pain and discomfort due to their oral condition (Q4). Except for 6 patients diagnosed with OLP, all other patients experienced mild burning sensations when consuming spicy food (Q5). About 16.66% of the patients experienced difficulties opening their mouths widely (Q6). More than half of the patients declared their taste sense didn't change much or at all. Eight patients (26.66%) dealt with some limitation in eating desired foods (Q7), 11 patients (36.66%) somewhat enjoyed their meals (Q8), and 12 patients (40%) reported no dryness of the mouth (Q10).

Furthermore, the assessment of psychological and social well-being indicated that 17 patients (56.66%) were scared about the possibility of their oral condition progressing to cancer (Q15). Almost half of the patients believed their oral condition had minimal or no effect on their relationships with family and friends (Q13). Furthermore, 66.66% of the patients (n=20, Q17) indicated they felt little to no embarrassment when eating at social events, like parties and functions (tab. IV).

The impact of treatment on daily life (tab. V) was investigated, revealing that a significant number of patients expressed satisfaction with their treatment (Q19). With the exception of 5 patients (16.66%), the majority reported experiencing only mild or no pain following their treatment (Q18). However, 19 patients (63.33%) noted that their daily routines were disrupted by their treatment appointments (Q20).

In the present study, it was found that patients with oral lichen planus and leukoplakia had a statistically significantly lower quality of life compared to patients with actinic cheilitis (p=0.038) (tab. VI). Similarly, gender differences were observed, with females reporting lower quality of life scores than males (fig. 1). Additionally, the analysis revealed that patients with a high school education had an adequate quality of life (fig. 2).

DISCUSSION

In this study, we analyzed the impact of three distinct OPMDs on the quality of life. According to available literature, this is the first study using a specific tool to compare QoL between the three most common OPMDs (leukoplakia, oral lichen planus, and actinic cheilitis) in Romania. The response rate was remarkable, with all patients agreeing to participate.

According to the OPMDQoL assessment, the first subscale showed that patients with OLP faced statistically significant difficulties in obtaining a clear diagnosis compared to those with OL or AC. This difference can be attributed to the fact that actinic cheilitis is clearly related to prolonged UV radiation exposure, while the etiopathogenesis of oral lichen planus is unclear and multifactorial, involving anxiety, stress, genetic factors, and associations with various systemic diseases. The multifactorial complexity of OLP complicates the diagnosis for dentists.

Participants diagnosed with oral lichen planus or oral leukoplakia exhibited elevated levels of physical and functional limitations in comparison to those with actinic cheilitis. This disparity may be due to the multiple signs and symptoms associated with these conditions, such as pain and burning sensations in the case of OLP and impaired taste perception for patients with OL, symptoms that are not a major concern for patients diagnosed with AC.

In a study published by Tadakamadla *et al.* (8), patients diagnosed with OL reported low scores in this subscale because some were diagnosed incidentally at an early stage during regular dental check-ups. In our case, most of these lesions are unfortunately ignored by patients in the early stages due to the lack of pain, leading to their presentation to the doctor only in advanced stages.

One of the remarkable aspects of this study was that all three OPMDs had similar scores for psychological and social well-being, indicating that the potentially malignant nature of the disease impacted this aspect of their lives. The majority of patients reported feeling frustrated (with 59.99% responding “quite a bit” and “very much”), experiencing some level of depression, and noting that their condition had an impact on their overall life satisfaction. Their primary worry was on the potential for the oral condition to progress into malignancy. Nevertheless, the patients did not notice any negative impact on their social interactions with family and friends, and they did not feel any discomfort when at work, parties, or other social events.

Prolonged treatments without a definitive cure are stressful for OPMD patients. However, no significant differences were observed between the three studied groups regarding the subscale effect of treatment on daily life. Similar results were reported by Kapur *et al.* (15), who compared scores from 45 patients treated surgically for OPMD. Ashshi *et al.* (16), following a 5-year study (2021-2018) at the University of Pennsylvania on a group of 100 patients (53 diagnosed with OLP), presented scores higher than those with associated epithelial dysplasia.

Female patients exhibited lower overall OPMDQ scores, indicating a reduced quality of life, a finding consistent with other studies (8,11,17,18). This result is expected, as women are more prone to anxie-

ty and depression (19).

The limitations of the present study must be acknowledged, particularly regarding the generalizability of the findings. The study sample was composed of subjects from a single teaching hospital in Romania, which may limit the applicability of the results to all OPMD patients in the country. However, the sample size was sufficient to draw valid conclusions and inferences representative of the target population under study.

CONCLUSIONS

Patients with oral lichen planus had higher values in the difficulties with diagnosis subscale than patients with oral leukoplakia and actinic cheilitis. OLP and OL greatly affect the quality of life of those affected, whereas the impact of AC was relatively minor. Patients with AC also had better scores on physical and functional limitations than those with OL and OLP. There were no differences between the three oral conditions with the potential for malignant transformation in the subscales effect of treatment on daily life and psychological and social well-being and a large number of patients declared themselves satisfied with the treatments they received. Therefore, the OPMDQoL instrument can be considered useful in monitoring treatment response. In particular, this tool helps clinicians understand the psychological and social impact of OPMD on their patients' lives.

This information has the potential to motivate patients to quit their bad habits and follow through with treatment. They also contribute to improving treatment outcomes, patient care, oral health education and research.

CONFLICT OF INTEREST AND FUNDING

The authors declare no conflicts of interest. This research received no external funding.

CLINICAL AND RADIOLOGICAL STUDY ON PERI-IMPLANT STATUS IN POSTERIOR IMPLANT-SUPPORTED PARTIAL FIXED DENTURES (Abstract). **Aim** of this study was to evaluate the clinical and radiological status of the peri-implant tissues in patients treated with posterior implant-supported partial fixed dentures. **Materials and methods:** The retrospective research was conducted on a cohort of 48 patients (mean age 63.04 ± 10.723 years). The study group included patients with posterior edentulism treated by implant-supported metal-ceramic fixed prosthetic restorations. Socio-demographic data (gender, age group) and anamnestic data were collected on: smoking status; periodontal grade; compliance to the supportive periodontal/peri-implant therapy; OHI index. Clinical and radiological parameters were assessed for 166 implants to establish the status of the peri-implant tissues and prevalence of peri-implantitis. **Results:** 45.8% of patients and 19,9% of implants were diagnosed with peri-implantitis. Significant statistical differences were found between implants without peri-implantitis and implants with peri-implantitis for gender ($p= 0.022^{*}$), age group ($p= 0.018^{*}$), smoking status ($p= 0.007^{**}$), OHI index ($p < 0.001^{**}$), periodontitis stage ($p < 0.001^{**}$), and compliance to periodontal/peri-implant support therapy ($p<0.001^{*}$). **Conclusions:** Although peri-implantitis affects almost half of the patients (45.8%), the proportion of individual implants affected is lower (19.9%). Incidence of peri-implantitis was significantly lower to patients with good oral hygiene, non-smokers, low grade periodontal disease, or patients compliant with periodontal/peri-implant support therapy. **Keywords:** POSTERIOR EDENTULISM, IMPLANTS, PERI-IMPLANTITIS.

INTRODUCTION

Implant-supported posterior partial fixed dentures have provided significant improvements in function, aesthetics, and patient satisfaction when compared with classical fixed prosthetic therapy, while prosthetic success rates were not significantly different between the tooth- and implant-supported posterior fixed partial dentures (1-3). However, various factors that lead to peri-implantitis can compromise the long-term stability of dental implants, which can emerge as primary complications impacting implant therapy success (4, 5). The osseointegration of implants can be impacted by biological, mechanical, or technical complications (6-8). Evaluating peri-implant soft tissues status is essential for the early detec-

tion of inflammation signs, such as edema or bleeding, which may indicate the initial stages of peri-implantitis. Monitoring peri-implant bone through periodic radiographs helps identify bone loss and assess implant stability, preventing advanced complications (9). Preventively, ensuring rigorous oral hygiene, scheduling regular professional cleaning sessions for implant surfaces, and reeducating the patient on proper brushing techniques are crucial. In early peri-implantitis, non-surgical treatments, such as mechanical debridement and the use of antimicrobial agents, can halt the progression of inflammation and prevent bone destruction. Thus, understanding the peri-implant condition in patients with implant-supported partial fixed dentures is crucial for developing effective preventive measures and non-surgical therapeutic protocols to enhance implant survival rates and overall oral health outcomes (10).

The **aim** of this study was to evaluate the clinical and radiological status of the peri-implant tissues in patients treated with posterior implant-supported partial fixed dentures.

MATERIALS AND METHODS

The retrospective research was conducted on a cohort of 48 patients (age: mean age 63.04 ± 10.723 years, range 40-84 years; gender: 22 men, 26 women). The study included patients treated with posterior implant-supported metal-ceramic fixed prosthetic restorations (FPR-IP) 166 implants). The mean follow-up was 6.19 yrs. (range 5-8 yrs.). All subjects were selected from a pool of patients treated by the same implantologist and oral surgery specialist, performing bone addition procedures, implant surgery and prosthetic restorations. Prosthetic loading was performed 3 months after implant stage for patients who did not require alveolar bone addition, and 4-9 months for patients who required bone addition. Inclusion criteria: patients with age over 18 yrs.; posterior edentulism (Kennedy Class I and II); metal-ceramic fixed partial dentures with implant-support (FPR-IP); follow-up 5-8 yrs. Exclusion criteria: cantilever-type FPR-IP; aggressive periodontitis in periodontal history; systemic diseases impacting peri-implant tissues (uncontrolled diabetes mellitus, osteoporosis, metabolic disorders); antibiotic therapy in the last 6 months. The study was conducted in accordance with the requirements of the Declaration of Helsinki from 1975, revised in 2008. Written informed consent was obtained from the enrolled subjects. Socio-demographic data (gender, age groups: 40-60 yrs.; > 60 yrs.) and anamnestic data were collected on: smoking status (smokers; non-smokers); periodontal status (periodontal grade according to the Classification of Periodontal and Peri-Implant Diseases and Conditions, World Workshop 2017); compliance to the supportive periodontal/peri-implant therapy; index OHI (Oral Hygiene Index). Patients were classified into four stages of periodontal disease (I, II, III, and IV) according to the classification to the Classification of Periodontal and Peri-Implant Diseases and Conditions (World Workshop 2017) (11). Patient compliance with periodontal/peri-implant supportive therapy (PST) was evaluated according to the recall intervals proposed by Monje *et al*. (2014) (12): compliant patient (attends PST sessions at intervals of ≤ 5 months); occasional compliant (attends PST sessions at intervals of > 6 months); non-compliant patient. Clinical data on peri-implant soft tissues were collected by clinical examination (13).

Peri-implantitis was diagnosed according to the following criteria (14-15): clinical signs of peri-implant inflammation (erythema, edema, bleeding on probing, and/or suppuration); bone loss of at least 3 mm visible radiographically. Radiological examination was performed by CBCT (Sirona Orthophos XG). Measurements were made by an independent radiologist who was not involved in the study. The peri-implant marginal bone loss (MBL) was calculated at the mesial and distal aspects of each implant using the Sidexis XG/DVT application (Dentsply/Sirona): the distance between the implant-abutment interface and the level of peri-implant marginal bone loss. The highest value was used as a reference for determining the degree of peri-implant bone loss.

Statistical Analysis

Descriptive statistics including frequencies, means and standard deviations were calculated for demographics, clinical parameters, and marginal bone loss. The comparison of the qualitative variables between test group and control was performed by using Chi-squared test. Chi-square test was used to examine the statistical differences between implants with peri-implantitis and healthy implants. All tests of significance were evaluated at the 0.05 error level with *SPSS version 27.0* (IBM, Armonk, NY, USA).

RESULTS

At the patient level, 54.2% of patients are healthy or exhibit a state of peri-mucositis (without peri-implantitis), while 45.8% of patients have peri-implantitis, indicating a significant proportion of affected cases at the individual level. At the implant level, 80.1% of implants are classified as healthy or with peri-mucositis, representing the majority of the analyzed implants, while 19.9% of implants show peri-implantitis. This result reflects a lower incidence of this condition at the implant level compared to the patient level (tab. I).

Significant statistical differences were found between patients without peri-implantitis and patients with peri-implantitis for OHI index (0-1 *vs.* 2-3) ($p= 0.011^{*}$), periodontitis grade ($<0.001^{**}$), and PST compliance (compliant vs. non-compliant) ($p=0.003^{**}$) (tab. II).

Significant statistical differences were found between implants without peri-implantitis and implants with peri-implantitis for gender ($p= 0.022^{*}$), age group ($p= 0.018^{*}$), smoking status ($p= 0.007^{**}$), OHI index ($p < 0.001^{**}$), periodontitis stage ($p < 0.001^{**}$), and PST compliance ($p< .001^{*}$) (tab. III).

DISCUSSION

While any implant present in the oral cavity, requiring additional treatment, is considered a "surviving" implant (16), "success" of a dental implant is associated with implants that are functional and satisfactory for patients. Criteria for a successful implant are as follows: immobility, absence of peri-implant bone loss on radiographic images, attached gingiva width ≥ 2mm, absence of peri-implant infection (17). We aimed to evaluate of the clinical and radiological parameters directly associated with peri-implantitis definition as provided by Heitz-Mayfield *et al*. (2018) (14) and Renvert *et al*. (2018) (15). In the investigated group, we observed a peri-implantitis prevalence rate at the implant level of 19.9%, higher than prevalence reported by research groups as follows: 7.3% (18), 9.1% (19), 9.8% (20), 9.83% (5), 9.6% (21), 13.5% (26), and 16% (24). Other research groups reported higher values compared to our results such as 23% (24) and 24,9% (25). At the patient level, we found 45.8% of patients with at least one implant affected by peri-implantitis. Other research groups reported mean values of 13.3% (26), 15.1% (18), 16.3% (19), 18.8% (21), 19.83% (5), 26% (23), 37% (22), and 45% (23). A review found that the prevalence of peri-implantitis ranges from 4.7% to 43% at the implant level and from 8.9% to 56% at the patient level (27). The wide variability in peri-implantitis prevalence rates can be attributed to differences in case definitions and evaluation criteria used by various research groups. However, in our study, the prevalence of peri-implantitis can be explained by the lower compliance of patients with periodontal/peri-implant supportive therapy. Regarding the distribution of peri-implantitis cases based on socio-demographic and population factors, statistically significant differences were observed between the percentages of implants without peri-implantitis and those diagnosed with peri-implantitis among smokers ($p = 0.007^{**}$), oral hygiene levels (OHI index) ($p < 0.001^{**}$), the stage of periodontal disease ($p < 0.001$**), and patient compliance with PST ($p < 0.001$**). The correlation between smoking and increased likelihood of peri-implantitis remains unclear (28). However, some authors categorize smoking as a risk factor as smoking changes the composition of the periodontal microbiota, impacting also the immune system, and increases the incidence and progression of periodontal diseases

associated with higher risk of tooth loss and implant failures (29). Patients with a history of periodontitis who do not fully adhere to supportive periodontal therapy have a significantly higher frequency of severe peri-implantitis cases requiring surgical procedures and/or antibiotic treatments (30).

CONCLUSIONS

Although peri-implantitis affects almost half of the patients (45.8%), the proportion of individual implants affected is lower (19.9%). Incidence of peri-implantitis was significantly lower to patients with good oral hygiene, non-smokers, grade I-II periodontitis, and patients compliant with periodontal/peri-implant support therapy.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

SPINAL METASTASES IN THE MOST COMMON CANCERS (Abstract): The **aims** of this study are to identify the underlying causes of spinal injuries and the molecular subtypes which are involved in the production of these pathologies. **Materials and methods**: This study is a retrospective one, which covered a period of four months (from January 1st to April 30th, 2015), and involved a total of 50 patients who were diagnosed with non-traumatic spinal cord injuries. These patients received treatment at the "Prof. Dr. N. Oblu" Emergency Clinical Hospital in Iași. **Results**: Despite having a group of just 50 patients we also managed to identify several key factors implicated in bone dissemination of the primary tumor: skeletal homotropism, vertebral bone composition, genetic and epigenetic alterations, bone remodeling imbalance. **Conclusions:** The study highlights the need for a multidisciplinary approach to manage spinal metastases effectively. The interplay between cancer progression, bone health, and patient's quality of life, can help healthcare providers to develop more comprehensive management strategies for individuals affected by metastatic disease. **Keywords**: BREAST CANCER, SPINAL METASTASES, PRIMARY TUMORS, BRONCHOPULMONARY CANCER.

INTRODUCTION

According to alarming data published by the World Health Organization (WHO), the rate of spinal bone metastases in the structure of cancer morbidity has increased significantly over the last 10 years, exceeding 70%, and in the last 2 years has even reached 85%.

This worrying trend places bone metastases in third place in terms of frequency among metastases, second only to lung and liver metastases. It is also worth noting that bone metastatic tumors occur 35-40 times more frequently than primary bone tumors. Metastatic cancer of the spine is an increasingly common problem due to significant advances in the treatment of primary cancers (1-3).

In cases of spinal metastases, the thoracic region is most frequently affected,

accounting for nearly 70% of cases, with a predilection for the T10 vertebral level. Approximately 25% of spinal metastases are found in the lumbosacral region, particularly around the L3 level. The cervical spine is less commonly involved, representing only about 15% of cases. At the vertebral level, the areas most commonly impacted by metastases are the vertebral body and pedicles, which are involved in 85% of cases. The paravertebral space (10-15%) and the epidural and intramedullary/intraspinal spaces (less than 5%) are less frequently affected.

Notably, the posterior part of the vertebra tends to be affected first, followed by the anterior part (2). Metastatic lesions in the spine can present as osteolytic, osteoblastic, or mixed. Spinal tumors are clinically manifested by significant pain, which is the primary reason for referral, along with neurological signs of spinal cord compression by the tumor mass and local or regional spinal deformity. The location of the pain corresponds to the site of the tumor and varies in intensity, progressively worsening over time, influenced by a number of intrinsic and extrinsic factors (2-5). Severe bone destruction can cause pathological fractures, spinal instability, and deformities, which may lead to the most serious complication-spinal cord compression. The onset of neurological symptoms is influenced by factors such as the location of the metastatic tumor on the spine, its position relative to the spinal cord, the speed at which compression occurs, and the vascular anatomy of the spinal cord in the affected area (3). These symptoms usually appear in the later stages and are marked by motor or sensory deficits, along with issues related to sphincter control. Spinal metastases, which affect approximately 70% of cancer patients, are a leading cause of mortality. Autopsy studies reveal alarming statistics, with spinal metastases present in 90% of prostate cancer cases, 75% of breast cancer cases, 55% of melanoma cases, 45% of lung cancer cases, and 30% of kidney cancer cases. Clinically, spinal metastases are most commonly associated with lung (21%), prostate (19%), and breast (12%) cancers, necessitating targeted medical interventions (4). Spinal metastases from breast cancer, like those from other cancers, can cause local pain, spinal instability, pathological vertebral fractures, spinal cord compression, neurological damage, and paralysis, all of which significantly impact patients' quality of life and reduce their lifespan. Accurate histopathological diagnosis is critical to identify the cancer subtype and the genetic mutations involved, guiding the selection of targeted therapies and specific immunotherapy. Percutaneous biopsy is a safe and effective method for obtaining tissue samples needed for diagnosis. The success of this procedure depends on several factors, including the suspected diagnosis, the size and location of the lesion, the imaging guidance used, the operator's experience, the available equipment, and the chosen approach (2-8).

This study aims to identify the underlying causes of spinal cord injury and the molecular subtypes involved in causing these pathologies.

Spinal injuries affect a significant number of people and significantly limit their quality of life.

MATERIALS AND METHODS

This retrospective study, conducted over a four-month period (January 1st - April 30th, 2015), included 50 patients with spinal cord or spine non-traumatic injuries who were

treated at the "Prof. Dr. N. Oblu" Emergency Clinical Hospital in Iași. Initially, the study sample consisted of 58 patients diagnosed with spinal tumors. However, 8 patients were excluded based on the following criteria: lack of surgical treatment due to clotting disorders; severely compromised general health status; life expectancy of less than 3 months; severe associated comorbidities. Data collection and statistical evaluation were based on electronic medical records. Collected data included patient demographics (such as age at breast metastasis (BM) diagnosis), and morphological features of the primary cancer (location, cytopathological features, histopathological subtype (HP), and immunohistochemical (IHC) characteristics). Cytopathological examination was conducted on intraoperative smears, using small specimens obtained during surgery. A small sample (1-2 mm^3) of the biopsy specimen was placed on one edge of a clean, dry, labeled slide, then crushed with the edge of another clean, dry slide, applying sufficient pressure to spread the tissue into a thin film on both slides. The slides were immediately stained with 1% toluidine blue. The remaining biopsy sample was processed for fixation. Surgical specimens were fixed in a 10% neutral buffered formalin solution for 24 hours, dehydrated using acetone and xylene, and embedded in paraffin. Paraffin blocks were sectioned into 3-µm-thick histological slices, which were stained with Hematoxylin-Eosin (HE) for microscopic examination. Additional 3-µm-thick sections were prepared for IHC staining, following a standard immunohistochemical protocol.

RESULTS

The study showed a gender ratio of approximately 1.17: 1 (female to male), with an average age of 57.04 years and a range from 12 to 79 years. Regarding background classification, 52% of patients were from urban areas, while 48% were from rural areas. Ethnic distribution included 82% Romanians and 18% Roma individuals. In terms of education, 20% of patients had postgraduate degrees, 62% had university degrees, 14% had secondary education, and 4% had primary education. The study also examined the duration from the onset of pain to surgery. Surgery was performed within 1 month of pain onset for 56% of patients, between 1 and 3 months for 36%, between 3 and 6 months for 4%, and after more than 6 months for the remaining 4%. Additionally, the study analyzed the type of tumor and its location at various spinal levels. Classification by tumor type shows that 9 patients (18%) had primary tumors and 41 patients (82%) presented secondary tumors. According to tumor site in the spine, 8 patients had cervical (16%), 31 patients (62%) had thoracic, and 11 patients (22%) had lumbar localizations. Our study revealed specific preoperative clinical features of spinal tumor pathology such as spinal pain, paravertebral muscle contracture, radicular pain, paresis or paralysis of a limb, paraplegia and sphincter disorders. Results were categorized by gender.

In male patients, the most common source of metastasis was bronchopulmonary cancer (fig. 1), representing 70% of the analyzed subjects.

One spinal metastasis of small cell bronchopulmonary carcinoma was identified in the selected group of patients (fig. 2), a common cancer in smokers with a 5-year survival prognosis of less than 1% (9).

The incidence of prostate cancer ranks it second among the primary cancers we

encountered as the starting point for spinal metastases diagnosed in the analyzed males (figs. 3, 4). The biopsy revealed metastatic adenocarcinoma. The neoplastic cells were organized in cords and nests, with some areas exhibiting a cribriform growth pattern. These cells had hyperchromatic small nuclei, a few of which contained prominent nucleoli. Immunohistochemical staining showed positive results for prostate-specific antigen and prostate acid phosphatase, while the tumor was negative for CK 7, CK 20, TTF-1, and chromogranin.

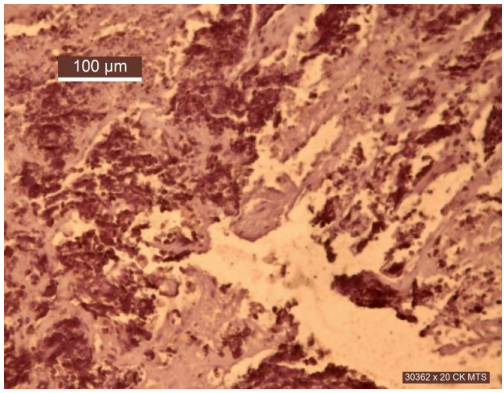

Fig. 1. Metastasis of undifferentiated bronchopulmonary carcinoma. Cytokeratin immunostaining, x200.

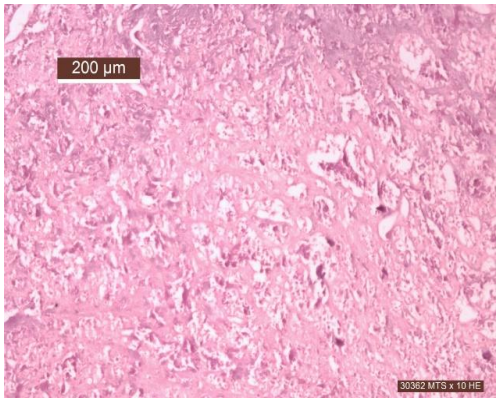

Fig. 2. Osteolytic metastasis of small cell carcinoma. HE staining x100.

After the surgery, the patient was referred to radiation oncology, where he received a total radiation dose of 20 Gy in five fractions, targeting the region from L4 to S3. During the three-month follow-up visit, the patients reported increased strength in his legs and noted improvements in his ability to walk.

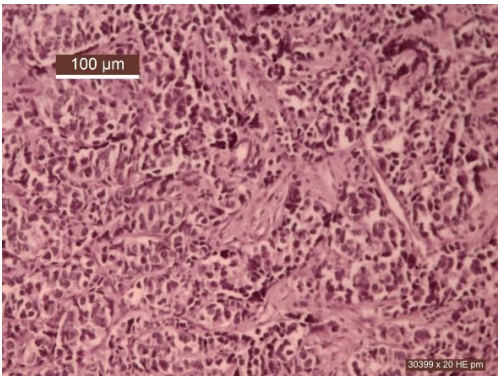

Fig. 3. Metastasis of moderately differentiated prostatic adenocarcinoma in a 68-year-old man. The preserved tubular structure is noted. HE staining, x200.

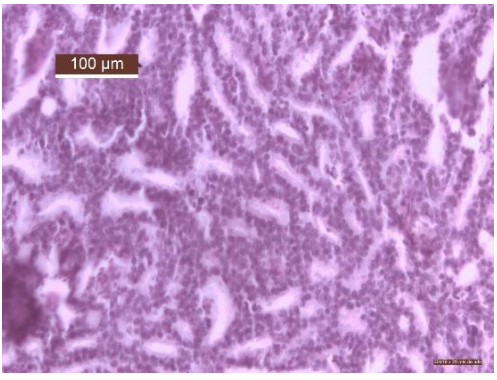

Fig. 4. Metastasis of prostatic adenocarcinoma. HE staining, x200.

As for the female group, breast cancer was the most frequent cancer and 60% of them were over 60 years old (figs. 5, 6, 7). No breast cancer was identified in the male group.

We present in figure 5 a metastasis of ductal breast carcinoma in a 60-year-old woman.

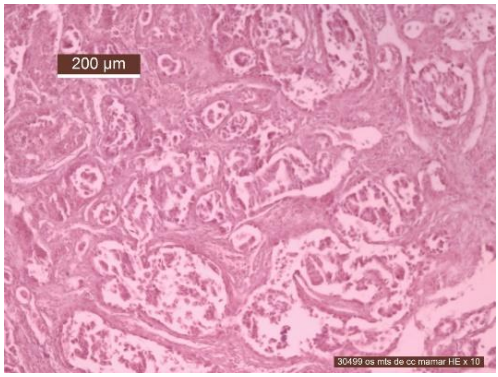

Fig. 5. Osteolytic metastasis of ductal carcinoma. HE staining, x100.

In figure 6 we can see the same metastasis at a higher magnification to note the partially preserved ductal architecture.

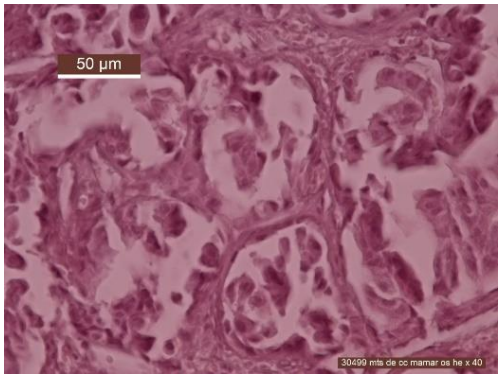

Fig. 6. Spinal metastasis of ductal breast carcinoma in a 60-year-old woman. HE staining, x400.

We considered it appropriate to analyze the parameters recorded in relation to the molecular subtype. For this purpose, we divided the total number of patients into 4 groups according to molecular subtype.

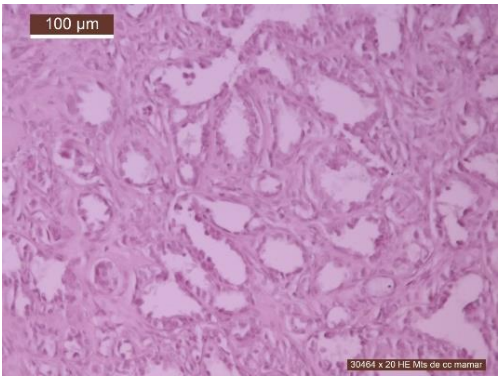

Fig. 7. Spinal metastasis of tubular breast carcinoma in a 68-year-old woman. HE staining, x200.

Based on molecular markers, breast cancer can be classified into molecular subtypes as follows (4, 11):

- Luminal type A is the most common subtype and is characterized by strong ER+ and/or PR+ but HER2- immunostaining. In terms of HP, it has a lower grade (low Ki67 LI) and is hormone responsive with a good prognosis. Type A luminal disease generally only requires endocrine therapy.
- Luminal type B is characterized by ER+ and/or PR+ and HER2+ immunolabels. It correlates with higher grade tumors (high Ki67 LI) and has a worse outcome compared to luminal type A, but also like luminal type A, this type B could be treated with endocrine therapy and chemotherapy.
- HER2+, but ER- is less common, being diagnosed at a younger age. Such cases have a high-grade histopathology and an aggressive outcome, but this outcome could be improved with Herceptin.
- Basal-like type breast cancer (BC) or triple negative breast cancer (TNBC) is an aggressive subtype characterized by high-grade histopathology, propensity for metas-

tasis and a poorer prognosis. Young women are at risk of developing this subtype of BC. Targeted therapies are currently under investigation, but chemotherapy appears to be indicated for most patients.

• Triple-positive BC with ER+/PR+ and HER2+ is a new subtype that can be treated with anti-HER2 agents and chemotherapy.

In the studied group of 27 patients, a number of 16, representing 59.25% were classified in the Luminal A molecular type, while a number of 7 patients, representing 25.92% were classified in the Luminal B type. The fewest patients were classified as HER2 type, 4 patients representing 14.81%.

The distribution of patients according to histopathological type shows a majority number representing 73% classified as ductal, 18.1% as lobular, and 8.9% as mixed.

The second most common cancer in patients is bronchopulmonary cancer as the origin of cancer for the spinal metastases. Figure 8 shows a spinal metastasis with bronchopulmonary origin at the T8 vertebral body in a 61-year-old woman.

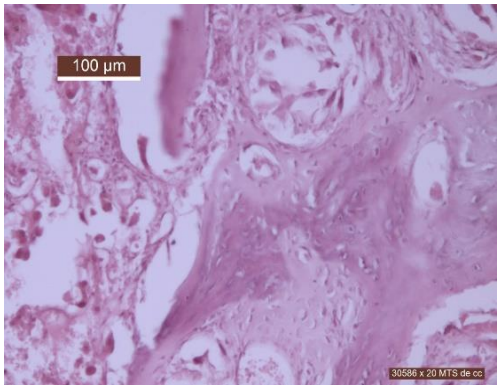

Fig. 8. Osteolytic and osteolytic metastasis of bronchopulmonary carcinoma. HE staining, x200.

DISCUSSION

Human bones are constantly in a state of self-renewal, undergoing a process known as remodeling. This intricate process involves a harmonious interplay between two types of cells: osteoblasts and osteoclasts. Under normal circumstances, these cells work in concert to maintain the bone strength and integrity of our bones (11-13).

However, in the case of metastatic lesions, this delicate balance is disrupted. The presence of cancer disrupts the bone's microenvironment, in favor of the osteoclasts. This disruption triggers a vicious cycle, where the weakened bones provide a favorable environment for tumor growth, which further accelerates bone destruction (12).

This disruption of the bone remodeling process can have serious consequences, leading to bone pain, fractures, and even loss of mobility. Other frequent dissemination sites are represented by lungs or liver (11-14).

Spinal metastasis is a common complication in advanced stages of malignant disease (9). Cadaveric studies reveal that 30% to 90% of cancer patients have spinal metastases at the time of death (10-15). In literature, the average patient age was 63.6 years. This aligns with data showing that the highest incidence of spinal metastases occurs between the ages of 40 and 65, a period when cancer risk is at its peak (15-16).

Spinal metastases typically affect the epidural space and/or vertebral column, while intradural extramedullary and intramedullary metastases are much rarer, accounting for only 5% to 6% and 0.5% to 1% of cases, respectively. The most common histological type involved is adeno-

carcinoma, most frequently originating from the breast and lung. The incidence of bone metastases is notably high in specific cancers.

Prostate adenocarcinoma, which affects up to 70% of men over 80, is the second leading cause of cancer-related death in men. Skull and spinal metastases occur in approximately 10% of prostate cancer patients, though intradural spinal cord tumors from prostate cancer are exceedingly rare. Spinal metastases represent a critical complication of advanced cancers, often leading to severe outcomes such as spinal cord compression, fractures, and neurological deficits. In our study, we analyzed the patterns and characteristics of spinal metastases in a cohort of patients, focusing on primary tumor types, clinical presentation, and outcomes following surgical interventions. The results were further examined in relation to broader literature on spinal metastases, specifically focusing on prostate and breast cancers, which are among the most frequent sources of bone metastasis (14-16).

Approximately 10% of patients with prostate cancer may experience spinal cord compression due to vertebral metastasis. Focal intradural metastasis of the prostate to the spinal cord, however, is extremely rare. An extensive search of English literature on *PubMed* revealed only nine documented cases of patients with intradural spinal cord metastasis (ISCM) from prostate cancer who underwent surgery.

In our study, prostate cancer was identified as the second most common primary tumor responsible for spinal metastasis in male patients. This aligns with established research, which indicates that approximately 10% of patients with prostate cancer develop spinal cord compression due to vertebral metastasis. The clinical presentation in our cohort often included back pain, paraparesis, or sphincter dysfunction, typical signs of vertebral involvement. Biopsy results revealed metastatic adenocarcinoma, with the neoplastic cells exhibiting hyperchromatic small nuclei and positive immunohistochemical staining for prostate-specific antigen (PSA) and prostate acid phosphatase. Following surgical intervention, many patients demonstrated notable improvements in strength and mobility, underscoring the importance of early detection and timely treatment (14).

Interestingly, while our study focused on extradural metastases, it is important to note that prostate cancer can also, though rarely, lead to intradural spinal cord metastasis (ISCM). Extensive reviews of English literature have found only nine documented cases of ISCM from prostate cancer, indicating the extreme rarity of this phenomenon. In contrast, extradural metastases are more common and are a significant cause of spinal cord compression in prostate cancer patients. This finding from the broader literature correlates with our study's emphasis on extradural vertebral metastases as a key cause of spinal pathology in men with prostate cancer. Thus, while ISCM remains a rare presentation, vertebral metastasis leading to spinal cord compression is a frequent and serious concern in prostate cancer patients (10-19).

In our female cohort, breast cancer was the most frequent primary tumor causing spinal metastases, particularly among women over 60 years old. This finding is consistent with data showing that 60-75% of women with advanced breast cancer develop bone metastases. This cancer type is the most frequent cause of bone metastases in women globally. Studies show that

60-75% of women with advanced breast cancer develop bone metastases, with a higher risk in certain subtypes (19). Our study revealed that breast cancer metastases were commonly localized in the thoracic spine, leading to clinical presentations such as spinal pain, radicular symptoms, and in severe cases, paraplegia. The molecular subtype classification in our study provides further insight, with the majority of breast cancer metastases (59.25%) falling under the Luminal A category, followed by Luminal B and HER2-positive subtypes.

A large study analyzing electronic records from various cancer centers in the US found that breast cancer was the leading cause of bone metastases (36%), followed by lung cancer (16%) and colorectal cancer (12%) (20-22).

The identification of molecular subtypes in breast cancer plays a crucial role in understanding metastatic behavior. For example, Luminal A breast cancer is known for a slower progression and a better prognosis, which may explain its prevalence in older women in our study, while HER2-positive breast cancer, though less common, tends to exhibit more aggressive metastatic patterns.

In our study, the majority of women with spinal metastases from breast cancer had ductal carcinoma, which is known for its tendency to metastasize to bones, further reinforcing the connection between this cancer type and bone involvement.

Breast cancer's invasion to bones disrupts the osseous tissue natural rebuilding process, leading to osteolytic lesions. Cancer cells trigger this process by releasing molecules that activate osteoclasts and, interestingly, osteoblasts are also involved, as they also produce factors that stimulate bone breakdown (19). Breast cancer cells initiate the destructive process in the bone by secreting factors such as parathyroid hormone-related protein (PTHrP), which directly affect bone cells. PTHrP, a powerful activator of osteoclasts, is found at elevated levels in an overwhelming 90% of bone metastasis samples. (20). It is the impact of the cancer cells that seems to shift the balance toward tissue breakdown.

Key factors, including parathyroid hormone-related protein (PTHrP) and transforming growth factor-β (TGF-β), play crucial roles in the process of bone destruction associated with metastatic cancer. PTHrP acts as a potent stimulator of osteoclast activity, contributing to bone resorption and further tumor progression. Additionally, TGF-β, released during osteoclast activation, exacerbates the situation by promoting increased production of PTHrP, creating a vicious cycle that accelerates both bone breakdown and cancer advancement.

PTHrP's influence extends beyond bone breakdown. It can directly promote tumor cell growth and angiogenesis through autocrine signaling (21, 22). However, PTHrP's role in prognosis remains a controversy. While some studies suggest its presence in early breast cancer indicates a poorer outcome (22), others show a potential link to improved survival and fewer bone metastases (19-21).

For adding another layer of complexity, the transforming growth factor-β (TGF-β) is responsible. Released by activated osteoclasts, TGF-β further increases PTHrP production in cancer cells (19). This creates a vicious cycle: PTHrP stimulates osteoclasts, leading to bone breakdown and the release of more TGF-β, which in turn increases PTHrP production.

CONCLUSIONS

Cancer metastasis to bones represents a significant challenge in oncology, fundamentally disrupting the natural balance of bone remodeling. This disruption is primarily driven by the interplay between osteoblasts, which build bone tissue, and osteoclasts, which reabsorb it. In cases of metastatic disease, this balance is tipped toward bone breakdown, leading to weakened skeletal structures that further facilitate tumor growth.

In our study, we observed that prostate cancer is the second most common primary tumor responsible for spinal metastases in male patients. This finding aligns with the understanding that among the various sites affected by metastatic disease, spinal metastases are particularly prevalent, especially in advanced stages of cancer. The thoracic and lumbar regions are frequently involved, corroborating existing literature that highlights these areas as common sites for metastatic lesions.

The complications associated with spinal metastases, including spinal cord compression (SCC), fractures, and debilitating pain, pose significant challenges to patient care. The presence of SCC is particularly concerning, as it not only leads to severe neurological deficits but also substantially impacts the functional prognosis and overall quality of life. Our findings indicate that early detection and timely intervention are crucial for mitigating these risks and improving patient outcomes.

Given the serious complications associated with bone metastases, especially the risk of SCC, there is an urgent need for enhanced diagnostic strategies and effective treatment modalities. Interventions that focus on preserving bone integrity and preventing complications can lead to substantial improvements in patient well-being. For instance, surgical interventions aimed at alleviating SCC, followed by radiation therapy, have shown promise in restoring neurological function and enhancing mobility in patients with metastatic disease.

Furthermore, our study emphasizes the importance of understanding the underlying mechanisms of bone metastasis. As we unravel the complex interactions between cancer cells, bone remodeling processes, and the tumor microenvironment, we can better identify therapeutic targets. This deeper understanding is essential for developing innovative treatment approaches that not only address the metastatic lesions themselves but also mitigate the bone-related complications that arise.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

LONGITUDINAL CLINICAL STUDY ON THE PREVALENCE AND RISK FACTORS OF ROOT CARIES IN ELDERLY PATIENTS (Abstract): Dental caries remains one of the most common oral diseases, with a multifactorial etiology involving biological, behavioral, socio-economic, and age-related factors. In elderly patients, physiological changes, systemic diseases, polypharmacy, reduced salivary flow, and gingival recession increase susceptibility to root caries. The **aim** of this study was to evaluate the prevalence of coronal and root caries across different age groups and to identify the etiological factors involved in root caries by comparing caries experience and individual cariogenic risk in adult and geriatric patients. **Materials and methods:** The study included 293 patients examined at the Clinical Teaching Base of the Faculty of Dental Medicine Iași between 2022 and 2026. Clinical assessment included the evaluation of coronal and root caries, gingival recession, and DMFT index. **Results:** Socio-economic factors, systemic diseases, and medication were recorded using a standardized questionnaire. Cariogenic risk was assessed by determining salivary levels of *Streptococcus mutans* and Lactobacilli, resting and stimulated salivary flow, salivary buffer capacity, and caries susceptibility using the modified Snyder test. Statistical analysis was performed using Chi-square and Kruskal-Wallis tests, with the significance level set at $p < 0.05$. Coronal caries showed the highest prevalence in the 71-80-year age group, followed by the 51-60-years group. Root caries was also most frequent in the 71-80-years group, followed by patients over 80 years. DMFT values increased with age, mainly due to the "M" component, reflecting cumulative tooth loss. Systemic diseases, xerostomia-inducing medication, gingival recession, reduced salivary parameters, and increased microbial load were associated with higher cariogenic risk. **Conclusions:** Root caries in elderly patients has a multifactorial etiology, influenced by age-related oral changes, systemic conditions, medication, salivary dysfunction, gingival recession, and cariogenic microorganisms. These findings support the need for individualized preventive and therapeutic strategies in geriatric dental care. **Keywords:** ROOT CARIES, ELDERLY PATIENTS, GERIATRIC DENTISTRY, DMFT INDEX, CARIOGENIC RISK.

INTRODUCTION

Currently, across all medical fields, the emphasis is placed on prevention, aiming to limit disease onset or progression to advanced stages. In dentistry, dental caries remains the most common condition, characterized by high prevalence and a significant impact on patients' quality of life (1, 2). Although often perceived as a minor condition, dental caries is now recognized

as a complex, multifactorial process resulting from the interaction of biological, behavioral, and socio-economic factors (3, 4). Recent studies have shown that the development of dental caries is influenced by factors such as high sugar consumption, poor oral hygiene, reduced salivary flow, insufficient fluoride exposure, and low socio-economic status. In the geriatric population, these factors are amplified by physiological changes associated with aging, including decreased salivary secretion, alterations in salivary composition, reduced self-care ability, and the frequent use of multiple medications (5, 6). Furthermore, age-related systemic conditions, such as diabetes mellitus and cardiovascular diseases, may indirectly affect oral health, increasing susceptibility to caries, particularly at the root surface level. From a microbiological perspective, *Streptococcus mutans* and Lactobacilli play a key role in the etiology of dental caries, with their presence and levels being directly correlated with caries incidence and the intake of fermentable carbohydrates (7,8). Quantitative assessment of these microorganisms is therefore useful not only for evaluating cariogenic risk but also for estimating dietary carbohydrate intake. In addition to these species, other bacteria have been implicated in the carious process, including *Veillonella*, non-mutans oral streptococci (*S. mitis, S. oralis, S. gordonii*), and Actinomyces species, which are capable of acid production at low pH levels (9, 10). The association between these microorganisms and dental caries is closely related to carbohydrate consumption, which is essential for the initiation and progression of the carious process. Levels of *Lactobacillus* and *Streptococcus mutans* may vary significantly even following short-term dietary changes (11, 12). The metabolism of dietary carbohydrates by dental plaque leads to the production of organic acids, which cause demineralization of dental structures (13, 14). This process is particularly relevant at the root level, where cementum and dentin are less resistant to acid attack compared to enamel. Repeated exposure to an acidic environment alters the oral ecosystem, favoring the selection and proliferation of acidogenic and aciduric bacteria (15, 16). While the effects of acid stress on the oral microbiota have been extensively studied, the role of nutrient deprivation has received less attention (17, 18). Studies suggest that under conditions of reduced dietary intake, certain species such as *Streptococcus oralis* and *S. mitis* may proliferate by utilizing salivary glycoproteins as an energy source (19). In this context, the management of geriatric patients requires a comprehensive approach that integrates local, systemic, and behavioral factors. Monitoring these variables is essential for understanding the prevalence and risk factors associated with root caries, contributing to the development of effective preventive and therapeutic strategies tailored to this patient population (20).

The aim of this study was to evaluate the prevalence of coronal and root caries across different age groups and to identify the etiological factors involved in root caries by comparing the degree of caries experience and the individual cariogenic risk between adult and geriatric patients.

MATERIALS AND METHODS

The study was conducted on a sample of 293 patients who attended the Clinical Teaching Base of the Faculty of Dental Medicine in Iași between 2022 and 2026. All participants were included in the study

after providing written informed consent. Clinical examination was performed under standardized conditions, in the dental chair, ensuring adequate illumination and isolation of the operating field. Prior to evaluation, professional oral hygiene procedures were carried out, including manual or ultrasonic scaling followed by professional tooth brushing. The clinical assessment focused on the identification of coronal and root caries lesions, as well as the evaluation of gingival recession. Caries experience was quantified using the DMFT index. For the assessment of cariogenic risk, patients completed a standardized questionnaire that included data regarding socio-economic status, educational level, presence of systemic diseases, and associated medication, with potential impact on the carious process, particularly through alterations in salivary flow or carbohydrate content.

The analysis of local etiological factors included the determination of the Silness and Löe plaque index, evaluation of salivary microbiota, and assessment of salivary parameters. Bacterial load was assessed by determining the levels of *Streptococcus mutans* (Dentocult SM method) and Lactobacilli (Dentocult LB), using standardized microbiological tests.

Salivary parameters were evaluated by measuring resting and stimulated salivary flow rates, as well as buffer capacity, using the Dentobuff method. Salivary flow values were expressed in ml/min, while buffer capacity was assessed colorimetric ally according to the manufacturer's scale. Individual susceptibility to dental caries was determined using the modified Snyder colorimetric test (Arthur Alban), which evaluates the acidogenic activity of oral bacterial flora. The interpretation of results was based on color changes of the culture medium, reflecting acid production levels and, implicitly, cariogenic risk. By correlating clinical, microbiological, and salivary data, the study aimed to evaluate the prevalence of caries lesions and to identify the risk factors involved in the development and progression of dental caries, with a particular focus on root caries in elderly patients.

Statistical analysis was performed in *SPSS version 29.0.* The qualitative data were reported as absolute frequencies and percentages, and the quantitative data were reported as averages and standard deviations. The associations between qualitative data were investigated using the Chi-squared test. The differences between quantitative data in multiple samples were investigated using the Kruskal-Wallis test, after checking the values distribution condition of normality (using the Shapiro-Wilk test). The values of $p < 0.05$ were evaluated as statistically significant, and the values of $p < 0.01$ were evaluated as statistically highly significant.

RESULTS

In order to achieve the objectives of the study, the collected data were statistically analyzed and presented in tables and graphical representations to highlight the distribution of the study group and the prevalence of carious lesions according to the investigated parameters. The study group was characterized from a demographic perspective (gender and age), followed by the analysis of the distribution of coronal and root caries lesions across different age groups. Additionally, the relationship between demographic variables and the studied parameters was evaluated to identify potential statistically significant correlations.

The gender distribution of the study group (tab. I) showed a relatively balanced proportion between male (50.5%) and female patients (49.5%). The age distribution (tab. I) revealed a predominance of the 61-70-year age group (51.9%), followed by the 51-60-year (17.7%), 71-80-year (17.1%), and over 80-year (13.3%) groups.

TABLE I.
The demographical features of the sample

		n	%
Gender	male	148	50.5
	female	145	49.5
Age group	51 - 60 ys	52	17.7
	61 - 70 ys	152	51.9
	71 - 80 ys	50	17.1
	over 80 ys	39	13.3
Total		293	100.0

The comparative distribution on genders by age groups did not reveal statistically significant differences (Chi-square test, p = 0.165) (fig. 1). However, a predominance of male patients was observed in the 51-60 and 61-70 age groups, a relatively balanced distribution in the 71-80 group, and a predominance of female patients in the over 80 group.

Regarding the prevalence of coronal caries (tab. 2), the highest values were recorded in the 71-80-year age group (20%), followed by the 51-60-years group (19.23%), the over 80 years group (12.8%), and the 61-70-year group (8.5%). The prevalence of root caries was highest in the 71-80-years age group (10%), followed by patients over 80 years (5.1%), the 51-60-years group (3.8%), and the 61-70-years group (3.2%).

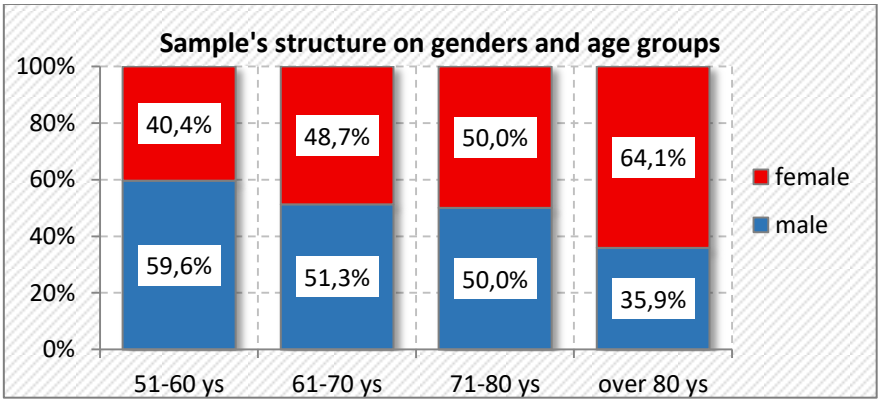

Fig. 1. Patients' distribution by genders and age groups

TABLE II.
The caries distribution by age groups

	Total		Age group								p-value†
			51-60 yrs.		61-70 yrs.		71-80 yrs.		over 80 yrs.		
	n	%	n	%	n	%	n	%	n	%

Root caries	14	4.7	2	3.8	5	3.2	5	10.0	2	5.1	0.279

†Chi-squared test

Following the analysis of caries prevalence, the study further evaluated the degree of caries involvement and identified the factors contributing to the development of root caries. In this context, clinical indicators such as the DMFT index, the presence of gingival recession, socio-economic factors, systemic diseases, associated medication, plaque index, and salivary microbiological parameters were comparatively analyzed.

Comparison of the level of caries involvement

The mean number of carious teeth varied according to age group, with the highest values recorded in patients aged 51-60 years (3.75 teeth), followed by those aged 61-70 years (2.91), 71-80 years (2.3), and over 80 years (1.72) (tab. III). The differences between age groups were statistically highly significant.

Enamel caries lesions showed the highest mean values in the 71-80-year age group (0.44), followed by the 51-60 (0.19), 61-70 (0.14), and over 80 (0.08) age groups. However, the differences between groups were not statistically significant.

For dentin caries lesions, the highest values were observed in the over 80 years age group (1.41), followed by the 51-60-year age group (1.35), 61-70 (0.97), and 71-80 (0.48), the differences between groups being again statistically highly significant.

TABLE III.
The level of caries by age groups

	Age group				Total M ± SD	p-value†
	51-60 yrs. M ± SD	61-70 yrs. M ± SD	71-80 yrs. M ± SD	over 80 yrs. M ± SD		
No. of carious teeth	3.75 ± 2.970	2.91 ± 2.969	2.30 ± 2.735	1.72 ± 1.820	2.80 ± 2.855	0.004**
No. of enamel caries	0.19 ± 0.445	0.14 ± 0.431	0.44 ± 1.514	0.08 ± 0.270	0.19 ± 0.734	0.513
No. of dentin caries lesions	1.35 ± 1.426	0.97 ± 1.617	0.48 ± 1.446	1.41 ± 1.712	1 .01 ± 1.591	<0.001**
No. of root caries lesions - located at cementum level	0.12 ± 0.379	0.64 ± 1.088	1.06 ± 1.476	0.56 ± 0.754	0.61 ± 1.075	<0.001**

†Kruskal-Wallis test, **p < 0.01 Statistically highly significant

Root caries lesions, located at the cementum level, were more frequent in patients aged 71-80 years (1.06), followed by those aged 61-70 years (0.64), over 80 years (0.56), and 51-60 years (0.12). These differences were also statistically highly significant.

The mean number of filled teeth was highest in the 51-60-year age group (2.98), followed by the 61-70 (1.18), over 80 (1.08), and 71-80 (0.32) groups (fig. 2). This distribution was also statistically significant ($p < 0.001$).

The DMFT index showed higher values in patients over 80 years and in those aged 71-80 years compared to the 51-60 and 61-70 age groups (fig. 3). These findings can be explained by an increase in the "M" component of the index, reflecting a higher number of missing teeth due to complications of dental caries. Additionally, patients from rural areas presented higher DMFT values compared to those from urban areas, regardless of age group.

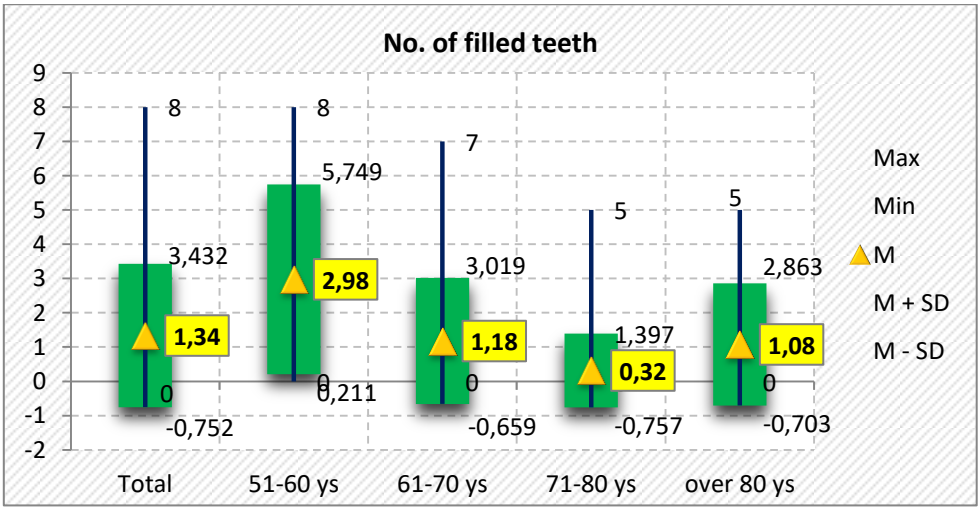

Fig. 2. Distribution of filled teeth by age group

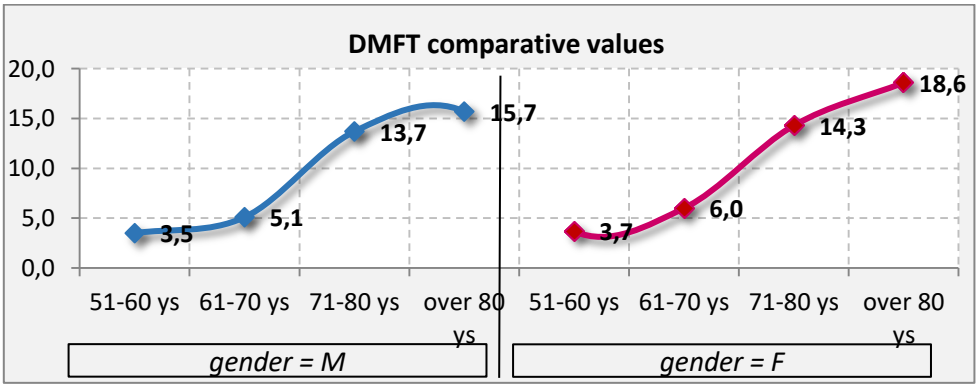

Fig. 3. Distribution of filled teeth by age group and place of residence

Identification of etiological factors of root caries assessment of individual cariogenic risk

Educational level. The distribution of patients according to educational level varied across age groups. In most groups, patients with secondary education predominated, with the highest proportions observed in the over 80-year group (64.1%) and the 51-60-year group (51.9%). These differences were statistically significant (Chi-square test, p = 0.011) (fig. 4).

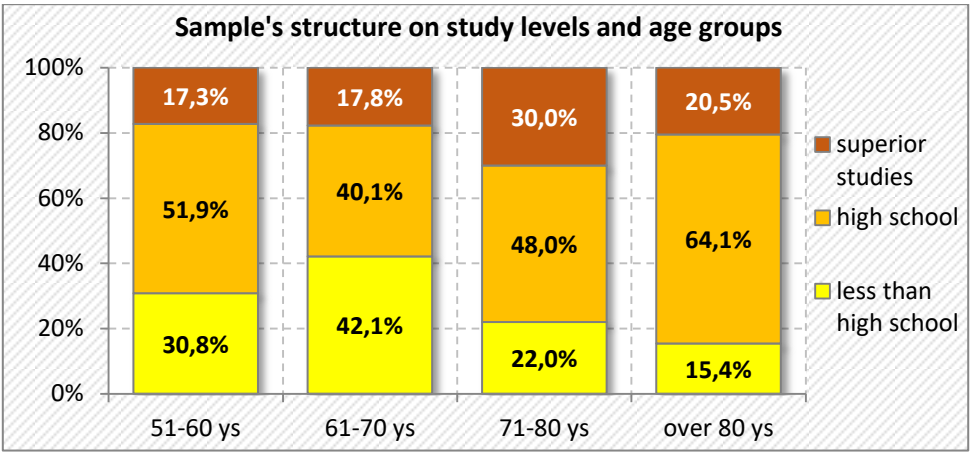

Fig. 4. Distribution of patients by age group and level of education

Place of residence. The majority of patients originated from urban areas, regardless of age group, with the highest percentages recorded in the 71-80-year group (76%) and the 61-70-year group (69.1%). However, the distribution according to place of residence was not statistically significant (Chi-square test, p = 0.075) (fig. 5).

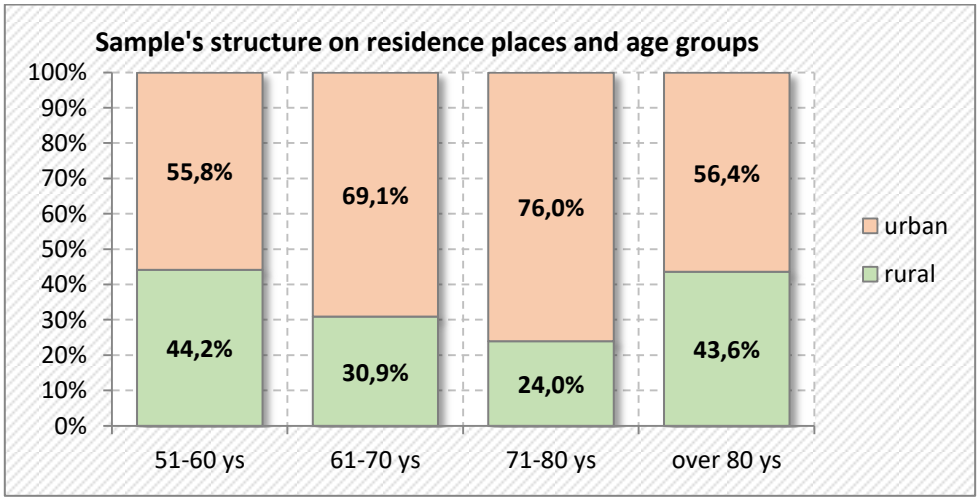

Fig. 5. Distribution of patients by age group and place of residence

Associated Systemic Diseases. Systemic conditions with a potential indirect impact on the carious process were more frequently observed in patients over 80 years of age, particularly renal, hepatic, pulmonary, neuromotor, osteoarticular, and cardiovascular diseases (tab. IV).

Associated Medication. Medication with the potential to reduce salivary flow was more frequently observed in older age groups (tab. V). In almost all cases (with only one exception, the antidepressants) the differences recorded between age groups were statistically highly significant, as it follows: the use of diuretics increased progressively, from 11.5% in the 51-60-year group to 79.5% in patients over 80 years; a similar trend was observed for vasodilators, used by 48.7% of patients over 80 years; beta-blockers were also more frequently used in patients over 80 years (79.5%), followed by the 71-80-year group (60%); ni-

troglycerin use was highest among patients over 80 years (53.8%), compared to younger groups; similarly, Digoxin therapy was most frequent in the over 80-year group (41%); sedatives use was also more prevalent among patients over 80 years (28.2%).

TABLE V.

The distribution of medications with potential to reduce salivary flow rate by age groups

Presence and Severity of Gingival Recession

The average number of teeth with gingival recession was higher in patients aged 51-60 years, followed by those aged 61-70, 71-80, and over 80 years. This decreasing trend with age may be explained by the reduction in the number of remaining teeth. The differences were not statistically significant (p = 0.063) (tab. VI). Regarding the severity of gingival recession, the highest average values were observed in the 71-80-year age group (2.81 mm), followed by the 61-70 (2.08 mm), over 80 (2.07 mm), and 51-60 (1.68 mm) groups; these differences were statistically significant (p = 0.006).

TABLE VI.

The level of caries by age groups

	Age group				Total M ± SD	p-value†

DISCUSSION

The results of the present study highlight that caries involvement exhibits an age-dependent profile, with a higher prevalence of coronal lesions in younger age groups and a progressive increase in root caries among elderly patients. This pattern is consistent with current epidemiological trends, which indicate a decline in dental caries in younger populations and an increased burden in older age groups (1).

In this study, the 51-60-years age group presented the highest number of carious teeth, whereas root caries lesions were more frequent in patients aged 71-80 years. This distribution supports the concept that, with advancing age, local factors such as root surface exposure and periodontal changes become major determinants of the carious process (2).

The increased DMFT values observed in older age groups, particularly in patients over 80 years, can be explained by the higher contribution of the "M" component, reflecting tooth loss as a consequence of caries complications. This finding suggests that, in elderly patients, cumulative caries experience is more relevant than the incidence of active lesions and is influenced by previous treatment history and access to dental care.

Regarding lesion localization, the predominance of dentin caries in the 51-60-year group and root caries in the 71-80-years group indicates a shift in the pattern of caries involvement with aging. Recent meta-analyses have reported a global prevalence of root caries of approximately 41%, emphasizing its importance in geriatric oral pathology (4).

Socio-economic factors showed a significant influence of educational level on patient distribution, while place of residence was not significantly associated with caries risk. These findings are partially consistent with the literature, suggesting that education influences oral health behaviors, whereas urban-rural differences are becoming less pronounced due to improved access to healthcare services.

Systemic diseases and associated medication play a crucial role in the development of root caries. In the present study, patients over 80 years exhibited the highest prevalence of systemic conditions and xerostomia-inducing medications (diuretics, beta-blockers, vasodilators, nitroglycerin, and digoxin). These results support previous findings that identify hyposalivation as a major risk factor for root caries, due to reduced buffering capacity and impaired antimicrobial function of saliva (5).

The higher prevalence of xerostomia in older age groups further supports the direct relationship between reduced salivary flow and increased cariogenic risk. Under these conditions, alterations in the oral microbiota favor the proliferation of acidogenic microorganisms, particularly *Streptococcus mutans* and Lactobacilli, which are implicated in the etiology of root caries.

Gingival recession represents another important determinant, through the exposure of root surfaces. Although the number of teeth affected by recession was higher in younger groups, the severity was significantly greater in patients aged 71-80 years. This finding suggests that the severity of gingival recession, rather than its mere presence, plays a key role in the development of root caries.

The plaque index showed higher values in the 61-80-years age groups, without statistically significant differences, indicating that poor oral hygiene remains a consistent factor across all age groups. Epidemiological studies have identified inadequate oral hygiene as one of the strongest predictors of root caries (6).

Microbiological analysis revealed a substantial proportion of patients classified as having moderate to high cariogenic risk, based on the levels of *Streptococcus mutans* and Lactobacilli. Recent studies confirm the role of these microorganisms in the initiation and progression of root caries, although the etiology is considered polymicrobial (2).

Overall, the findings of this study confirm the multifactorial nature of root caries, resulting from the interaction between local factors (dental plaque, gingival recession), systemic conditions (general diseases, medication), behavioral aspects (oral hygiene, diet), and biological factors (saliva, oral microbiota). Modern models of cariogenic risk assessment integrate these variables into predictive approaches aimed at prevention and personalized treatment strategies.

CONCLUSIONS

Caries involvement varies with age, with a predominance of coronal lesions in younger age groups and an increased prevalence of root caries in elderly patients, particularly in the 71-80-years age group.

The DMFT index showed an increasing trend with advancing age, mainly due to the "M" component (missing teeth), reflecting cumulative tooth loss associated with complications of dental caries.

Both systemic and local factors, including general diseases, xerostomia-inducing polypharmacy, and gingival recession, contribute significantly to the development and progression of root caries lesions.

Reduced salivary flow rate and buffering capacity in elderly patients represent key determinants in increasing caries susceptibility, especially at the level of exposed root surfaces.

Increased salivary microbial load, characterized by elevated levels of *Streptococcus mutans* and Lactobacilli, is associated with moderate to high cariogenic risk in the majority of patients.

The overall cariogenic risk is higher in older age groups, particularly in patients aged 71-80 years, confirming the multifactorial nature of dental caries and the need for individualized preventive and therapeutic approaches.

SELF-MEDICATION-A PUBLIC HEALTH PROBLEM IN ROMANIA NOWADAYS. THE FIRST QUESTS (Abstract): Self-medication is an important part of the health care system, designed to educate the population in the spirit of responsibility for their own health, to inform and to provide medical and pharmaceutical services. Self-medication has a high prevalence in Romania where people choose to treat themselves by fever, headaches, cough, cold, and pain. **The aim of the study** was to evaluate the situation regarding self-medication in general population, estimated with a questionnaire. **Material and methods**: The study was conducted on 100 respondents aged 18-60 years, patients of an individual family medicine cabinet in Iasi County, North-East Romania. The instrument was a questionnaire consisting of 28 items and structured in two parts: a first part evaluating the respondent's demographic and socioeconomic data, and a second part exploring patient's perception of self-medication, mainly the frequency of use and cause. **Results:** The demographic structure of the study group showed an increased frequency of persons aged 35-44 years (22%), female gender (64%), from urban area (85%); 65% of whom are graduates of upper secondary education, most of them employed (52%) and married (63%). Romanian respondents claim that self-medication is a self-administered treatment (50%), take medicines after consulting websites (32%), for sore throat and fever (24%), because of the lack of money (35%), most of them being anti-inflammatories (30%), unaware of the risks of self-medication (50%), but thinking that one of the main risks could be inappropriate administration (41%), choosing self-medication as first option (12%), but also ask for a physician (69%). **Conclusions:** Self-medication is influenced by the sociodemographic characteristics of individuals such as age, morbidity, health and attitude, stress, and social rules. Getting a look at the elephant meaning this big issue named self-medication, using a questionnaire applied to specific groups of population could an important aspect that can help healthcare professionals to provide personalized counseling based on the specific needs to prevent self-medication risks and adverse effects of inappropriately use of medicines. **Keywords**: SELF-MEDICATION, PUBLIC HEALTH, ANTIBIOTICS, QUESTIONNAIRE.

Self-medication is defined as the administration of medicines by consumers to treat symptoms and mild health disorders recognized by themselves. This definition was included in *Declaration of Alma-Ata*, adopted by UNICEF/WHO experts at Conference of Primary Care in 1978 ("*The people have the right and duty to participate individually and collectively in the planning and implementation of their health care.*") (1). One of the basic characteristics of self-medication is the patient's responsibility for own health, so that Association of the European Self-Medication Industry (AESGP) has replaced the term of "self-medication" with "responsible self-medication" in 1994. It is noteworthy that the self-administration of unqualified medicines (on the recommendation of friends, from the remnants of drugs purchased previously, etc.) cannot be qualified as self-medication and is contra-indicated, although such cases occur very often daily. The notion of self-medication implies improving health in the case of mild illnesses, chronic illnesses ingravescence, or first aid until the physician arrives (2-4).

Applying preventive measures to reduce the risk of illness, detecting symptoms at early stages to prevent illness or disease progression is defined as self-prophylaxis. Self-medication and self-prophylaxis are two parts of the *responsible self-medication* design concept and a component of the primary healthcare. It also included healthy lifestyle, smoking cessation, moderate alcohol consumption, correct medication management, etc. Self-medication is currently a constituent part of the healthcare system designed to educate the population in the spirit of responsibility for their own health, to inform and to provide medical and pharmaceutical services. Self-medication has a high prevalence in Romania where people choose to treat themselves from fever, headache, cough, and cold. The most common medicines used without prescription (OTC) are vitamins and supplements, cough and fever pills, analgesics and antibiotics. Many parents give medicines to their children without any medical advice (5, 6).

Sources of self-medication could be friends, relatives, neighbors, or pharmacists, previous prescriptions or suggestions from commercials. Self-medication could be described as the ability of the population to play an independent and informed role in terms of preventive, diagnosis and treatment activities management that concern themselves. There are many healthcare systems that encourage population for self-prophylaxis and self-care of minor diseases using responsible self-medication to reduce treatment costs, patient and physician time. One of the most important issues linked to self-medication could be the antimicrobial resistance, reported in developing countries where antibiotics are available without prescription, as well as serious incidents due to side effects. To decrease the frequency of them, healthcare professionals should take measures to claim responsible self-medication, achieved by a safe access to medications, correct indications for use and the accessibility of medical consult if needed (7).

The aim of this study was to evaluate the situation regarding the self-medication among a Romanian population group, based on the questioning of the patients. The secondary aims were to raise awareness of the importance of drug use safety issues and to assist professionals in detecting and reporting side effects or other drug-induced problems.

MATERIAL AND METHODS

The study was conducted on 100 respondents, as patients of an individual family medicine cabinet in Iasi County, North-East Romania, aged between 18 and 60 years. The method was the survey of opinion using as instrument a questionnaire consisting of 28 items and structured in two parts: a first part evaluating respondent's demographic and socioeconomic data, and a second part exploring patient's perception of self-medication, mainly the frequency of use and cause. The questionnaires were anonymous to give the participants the opportunity to express their opinions freely.

The questionnaire was handed to each patient separately, explaining the study purpose and taking the oral informed consent before the interview. This consent claimed that participants had no risk if they refuse to participate in the study or cease collaboration during the application of the questionnaire.

Data were processed using *SPSS 20.0.*

RESULTS

1. Demographic and socioeconomic characteristics of participants

Iasi County is in the North-East Romania, Europe, with a population of over 700,000 inhabitants, and a demographic and social structure like the whole geographic area. There is no specific regional pathology, but common colds, diarrheal diseases in young people, and cardiovascular diseases, diabetes mellitus, rheumatic disorders, dental and oncological pathology in elderly adults are predominant (8).

The demographic structure of the study group showed an increased frequency of persons 35-44 years (22%), female gender (64%), from urban area (85%); 65% of them are graduates of upper secondary education, most of them employed (52%) and married (63%) (tab. I, fig. 1).

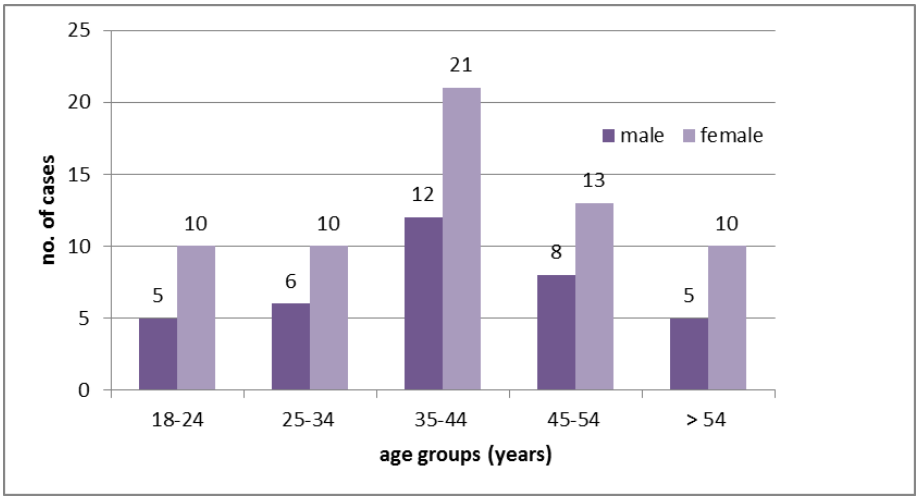

Fig. 1. Distribution by age and gender

2. First quests - items 7-15

Item 7: "Definitions of self-medication by patients". More than half of the respondents said they knew what self-medication means „self-medication treatment" (50%) or "independence in maintaining their own health" (24%). **Item 8:** "The initial source of information that urges the patient to self-medication"**.** 32% of respondents said they were taking medication after consulting websites. 30% of those considered the opinion of their family members about the selection of drugs. Only 11% were given self-medication because of viewing the advertisements (tab. II).

Item 9: "Pathological conditions for which self-medication was applied" were considered cold states (sore throat, cough, fever) - 24%, pains - 19%; headaches, insomnia, asthenia - 15%; dermatitis, acne, mycosis -14%; gastrointestinal tract disorders (vomiting, diarrhea) - 10%; avitaminosis - 6%.

Item 10: "Causes of self-medication". Among the reasons for the self-medication they mentioned: lack of money - 35%; advertising - 20%; permissive legislation - 11%; difficult access to medical services - 7% (tab. IV).

TABLE II

DISCUSSION

Self-medication is an important public health issue, especially in developing countries such as Romania, India, China, and countries where access to healthcare is costly, where it is one of the preferred ways of patients to treat their symptoms. Several studies have shown that self-medication can provoke delays in medical care, leading to paradoxical economic losses due to delayed diagnosis and delayed appropriate treatment. Also, self-medication can lead to drugs interactions that could be prevented if the patient consulted a physician at first. Self-medication for drugs such as antibiotics can lead to antimicrobial resistance (9, 10).

Self-medication is a widespread phenomenon, with an increasing incidence, difficult to quantify, affecting all age groups, but especially people over 65. As for adolescents and young adults, 35% of them use self-medication. Of those over the age of 54, 19% use self-medication. The risks of this practice in elder persons are the same as in younger individuals, but they occur much more frequently and have a higher severity due to the multipathology and multimedication often present in this category of patients as well as the fragility of elders. The study states that self-medication is more frequent among women in all age groups. According to our research, women with higher education and aged 35-49 are more likely to provide medicines to children without a medical consultation. The increasing prevalence of lifestyle and chronic conditions requires education regarding the treatment and effective communication strategies to allow patients to play an active role in chronic disease management or for motivational counseling (11, 12).

Medicines play a key role in ensuring or maintaining people's health, but they are not always used rationally. The rational use of medicines implies their appropriate use. This means that patients administer medications at appropriate, correct doses, when necessary, during the relevant period and at the lowest cost for them, avoiding unnecessary medications or whose use is unlikely to lead to health benefits (13).

More than 50% of countries do not carry a substantive policy to promote the rational use of medicines. In developing countries, less than 40% of patients from state sector and 30% of those from private sector are treated according to clinical guidelines. Excessive and irrational use of antibiotics leads to increased antimicrobial resistance, consequently a growing number of antimicrobial drugs become ineffective in the treatment of infectious diseases. Adverse drug reactions caused by abuse in their use, allergic reactions can lead to aggravation of the disease, undermining patient confidence in the healthcare system. Excessive use of a limited number of medications may result in their lack or inaccessible costs, undermined patient confidence. Unsatisfactory or negative results in treatment, caused by inappropriate use of drugs, may also undermine confidence (14-16).

The alpha coefficient, commonly referred to as *Cronbach alpha* (α), was proposed by the American psychiatric Lee J. Cronbach, in 1951. Although not the only indicator of fidelity, Cronbach alpha is by far the most used and most commonly reported in the literature. There is no absolute standard of the size that a Cronbach alpha coefficient should have to indicate an appropriate fidelity. Values around 0.90 are considered *excellent*, and around 0.80, *very good*, and those around 0.70, *appropriate*. The importance of the Cronbach alpha coefficient can be better understood if we place it on the terms of the relationship between validity and fidelity. A measurement can be reliable, but not necessarily valid. Validity refers to the accuracy of measurement, that is, to its ability to properly reflect what we want to measure and not something else (17).

CONCLUSIONS

Self-medication is influenced by the sociodemographic characteristics of individuals such as age, morbidity, health and attitude, stress, and social rules. Getting a look at the elephant meaning this big issue named self-medication, using a questionnaire applied to specific groups of population could an important aspect that can help healthcare professionals to provide personalized counseling based on the specific needs to prevent self-medication risks and adverse effects of inappropriately use of medicines.

MORPHOLOGIC, MOLECULAR, AND TAXONOMIC EVOLUTION OF RENAL CELL CARCINOMA: A CONCEPTUAL PERSPECTIVE WITH EMPHASIS ON UPDATES TO THE 2016 WORLD HEALTH ORGANIZATION CLASSIFICATION

The recently released 2016 World Health Organization classification now recognizes 12 distinct RCC subtypes, as well as several other emerging/provisional RCC entities. In this paper, the authors provide a conceptual framework for approaching RCC diagnosis and classification. The expanding number of recognized RCC entities in the 2016 WHO classification requires surgical pathologists to integrate clinical, radiologic, gross, and microscopic findings to successful differential diagnoses in RCC classification. In routine clinical practice, accurate RCC classification may have important implications for patients and their families, including prognostic risk stratification, targeted therapeutics selection, and identification for genetic testing (Udager AM and Mehra R. Morphologic, Molecular, and Taxonomic Evolution of Renal Cell Carcinoma: A Conceptual Perspective with Emphasis on Updates to the 2016 World Health Organization Classification. *Arch Pathol Lab Med* 2016; 140(10): 1026-1037).

AN UNUSUAL CASE OF CHOLECYSTODUODENAL FISTULA IN A NONAGENARIAN PATIENT (Abstract): Acute acalculous cholecystitis is a severe pathology of the gallbladder that associates high morbidity and mortality due to the age of onset and numerous comorbidities frequently seen in a nonagenarian patient. Complications such as cholecystoduodenal fistula is rarely seen in these patients and may be a burden in diagnosis due to atypical symptomatology. We reported a case of 91-year-old woman which was referred to our medical unit with epigastric pain, ferriprive anemia and weight loss and no prior history of gastrointestinal disorders. In the presence of anemia and epigastric pain an upper gastrointestinal endoscopy was performed showing a duodenal ulcer with benign histology. Repeated ultrasonography and computer tomography examinations were performed showing a hypoechoic mass with mixed structure on the topography of the gallbladder and a fistulous tract in direct contact with the duodenum. The diagnosis was difficult to obtain due to poor clinical symptomatology and the possibility of malignancies at this age, still after correlating the laboratory assessments with imaging data we concluded that it was a case of acalculous cholecystitis complicated with cholecystoduodenal fistula and pericholecystic abscess. Our patient was referred to the surgical unit and percutaneous cholecystostomy was performed as a low risk procedure with good outcome in case of our patient. **Keywords:** CHOLECYSTODUODENAL FISTULA, NONAGENARIAN, ACALCULOUS CHOLECYSTITIS.

Cholecystitis is one of the most common diseases of the gallbladder. It is defined as an inflammatory process of the gallbladder which occurs in 90 % of cases because of obstruction of the cystic duct from cholelithiasis defining the calculous form, and in 10 % of cases represented by the acalculous form (1).

Cholelithiasis has a similar incidence in Europe as in U.S., afflicting more than 20 million people annually (2). Due to its tight association with the presence of gallstones the prevalence increases with age, mostly seen in patients over 60-years-old. Recent researches relate to an increased prevalence of gallstones, up to 80 % in patients that are institutionalized, aged over 90 years (3-5).

A good prognosis is seen in patients with uncomplicated forms of cholecystitis without associating severe comorbidities, the development of complications such as perforation or gangrene negatively influencing the prognosis. Cholecystitis affects a wide spectrum of population and may

present different symptoms in extreme categories of age. The symptomatology may vary judging the age of onset, nonagenarians may experience poor clinical signs, without many key physical findings, the complication may occur silently in contrast with young population in which cholecystitis is associated with congenital comorbidities and presents a different clinical panel.

One of the most severe complication of acute cholecystitis is the perforation of the gallbladder usually seen in acalculous form due to underlying diseases which have a higher incidence in elderly patients (age >65 years) (6). Recent data reveal that in elderly patients, bilio-enteric fistulas complicated with liver abscess are rarely seen and the symptomatology may be atypical due to an increased number of comorbidities and reduced biological reserves. Also, the surgical treatment is controversial in these patients due to high mortality rates, percutaneous cholecystostomy (PC) being in some cases the most convenient and minimal risk procedure option in favor of laparoscopic cholecystectomy(LC) (7).

Taking in consideration the data presented in the literature, we intend to report a case of acute acalculous cholecystitis complicated with duodenal fistula and pericholecystic abscess in elderly patient.

CASE REPORT

A 91-year-old Caucasian woman, with prior history of diabetes type 2 and hypertension, was referred to our Institution of Gastroenterology and Hepatology in February 2017 for recent history of epigastric pain, lack of appetite, vomiting, nausea, and weight loss (3 kg in the last month), slow transit constipation without signs of gastrointestinal bleeding. The patient denied both alcohol and drug administration at home. Physical examination found pallor teguments, arrhythmic cardiac sounds and right upper quadrant localized tenderness. Electrocardiogram showed atrial fibrillation with no signs of ischemia, chest X-ray ruled out pleural and lung lesions.

Patient's first laboratory assessment showed severe ferriprive anemia (7 g/dL), leukocytosis (12×10^9/L), hyperglycemia (124 mg/dL), abnormal liver tests (TGP = 495 U/L, TGO= 459 U/L, GGT= 634U/L, total bilirubin =1.61 mg/dL, alkaline phosphates = 781 U/L), inflammatory syndrome (CRP= 6.43 mg/dL), amylase 73 U/L, lipase 70 U/L, and negative blood culture. Renal function and uric acid levels were within normal range. Tests for hepatitis C and B turned out negative. Abdominal ultrasound was performed showing a poorly defined hypoechoic mass with echogenic gas bubbles inside surrounding an indistinct gallbladder outline, no typical gallstones images were detected (fig. 1).

Intrahepatic biliary ducts were dilated at a maximum of 12 mm, the common bile duct with a diameter of 9 mm and no ascites was seen. To investigate the cause of severe anemia in the presence of epigastric pain, we performed upper gastrointestinal endoscopy that revealed an ulcer situated in the descending part of the duodenum with shallow fibrinous necrotic base and blood oozing in the nearby area (fig. 2). The ultrasound results and the endoscopic findings raised the suspicion of cholecystic abscess with duodenal fistula. To sustain our presumptive diagnosis, the patient undergoes abdominal computed tomography (CT) that showed a liquid hypodense mass, poorly demarcated, without identifying the gallbladder, gas bubble inside and in direct contact with the second part of the duodenum consisting with a cholecystoduodenal fistula (fig. 3).

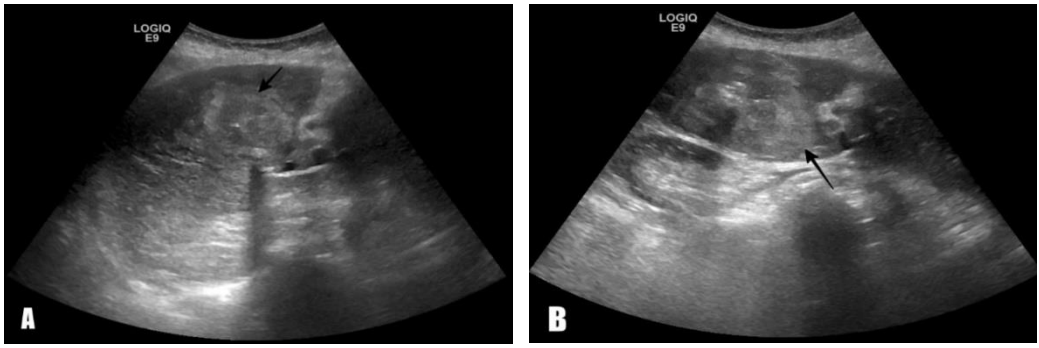

Fig. 1. A. Abdominal ultrasound showing in the examined window a hypoechoic liver mass with echogenic gas bubbles inside poorly demarcated on the topography of the gallbladder, dilated intrahepatic ducts. **B.** Abdominal ultrasound showing in the examined window the absence of gallbladder visualization.

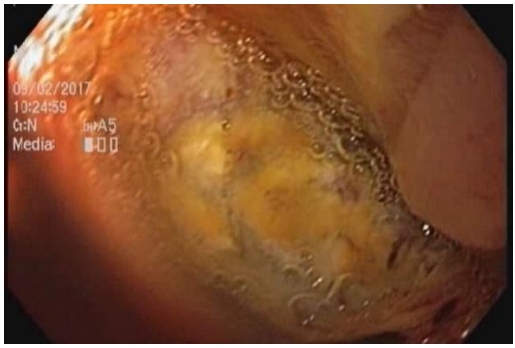

Fig. 2. Upper gastrointestinal endoscopy showing a giant duodenal ulcer in the descending part with shallow fibrinous necrotic base and blood oozing.

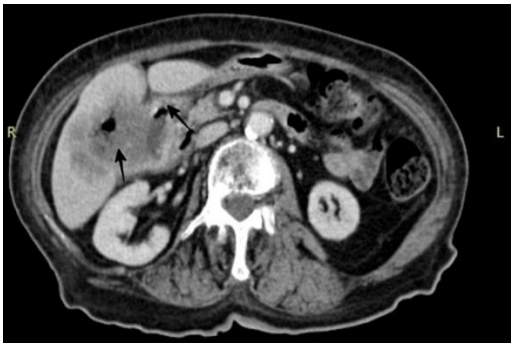

Fig. 3. Abdominal CT showing a pericholecystic abscess with duodenal fistula

At this point our suspicion of *acute acalculous cholecystitis* (AAC) complicated with pericholecystic abscess and duodenal fistula was confirmed and the patient was referred to surgical unit to assess the best treatment. In our unit, the treatment began with proton pump inhibitor (PPI) prescribed for the gastric ulcer, empirical antibiotherapy, iron replacement, volemic repletion and antalgic drugs.

Based on the age of the patient, the traumatic stress, atypical symptoms and the elevated risk of complications, the surgeons decided the PC is optimal as first line treatment instead of LC.

DISCUSSION

AAC is a severe condition with high mortality and morbidity with different clinic manifestation in comparison with the calculous form due to its multiple pathogenic mechanism, rarely seen in young and healthy patients (8-11). It is associated with an increased number of comorbidities such as ischemia, heart failure, diabetes mellitus, bile stasis, surgery and it has an atypical

onset in elderly patients with severe complications (gangrene, perforation) if it is misdiagnosed (12-14).

Ultrasound examination is needed in first stages of cholecystitis for a thoroughly diagnosis, but in some cases when complication occur such as gas formation in the wall or inside the gallbladder visualization can be impaired requiring computed tomography and for particular situations when direct observation of the fistulization tract in the adjacent organs, endoscopic retrograde cholangiopancreatography (ERCP) is to be considered a possible method of choice. One of the most severe complications of AAC is perforation of the gallbladder being first described by Duncan et al in 1884 and classified in three types, in the late nineties being updated by Anderson et al, adding the fourth stage consisting with cholecystobiliary fistula (15). The clinical symptomatology may differ judging the degree of perforation of the gallbladder, in type I peritonitis occurs, type II form pericholecystic abscess, type III and IV evolve with duodenal perforation and fistulization (16). In our case the perforation was a type III with atypical symptoms frequently seen in elderly patients.

Pain in the right hypochondrium, fever and leukocytosis may occur as classical symptoms, but in the case of our patient the fever was absent with negative blood cultures while the abdominal pain had epigastric localization. The clinical symptoms and the severe anemia required further investigations. The upper endoscopy findings showed a giant ulcer in the second part of the duodenum. Biopsies samples were taken from the margins of the duodenal ulcer to exclude the possibility of a malignant ulcerative tumor with perforation and fistula in the gallbladder.

In the elderly peptic ulcers are a frequent and a severe pathology with a risk of bleeding that increases constantly above age of 75 years. Comorbidities and the use of non-steroidal-anti-inflammatory (NSAI) drugs are the major risk factor in peptic ulcer, in 10 % of the cases bilio- duodenal fistulas being a severe complication. The medical history of our patient did not show NSAI drug administration and the comorbidities did not consist in a substantial risk of duodenal ulcer, the ulcerative process being the outcome of the bilio-duodenal fistula. Although there is a substantial risk of ulcers in elderly, in 90 % of cases fistulation occurs after the erosion of the wall of the gallbladder in the presence of a gallstone (15).

The lack of visualization of the gallbladder and a hypoechoic liquid mass with bubble gas described by the ultrasound firstly raised the suspicion of emphysematous cholecystitis with gas gangrene because of anaerobic bacterial infection. There were predisposing factors such as diabetes type 2 and ischemia judging the age of the patient and the cardiovascular risk factor. At the time of diagnosis, the clinical symptomatology was atypical but couldn't rule out the diagnosis of emphysematous cholecystitis. In this stage of diagnosis an improvement was brought by the CT scan. However, in our case the gas in the gallbladder could have been derived either from the fistula or could be formed in site of the gallbladder as a result of anaerobic bacterial infection, following that the result of analyzed drainage liquid collected in the surgical unit to conclude the nature of the gas formation.

As possible explanations for lack of visualization of the gallbladder we hypothesized some common conditions such as

previous cholecystectomy, unusual shape or positioning, obscure image due to gas in the gut or contraction of the gallbladder due to lack of food intake frequently seen in elderly patients (17). The medical history and abdominal ultrasounds previously performed before the admission in our hospital showed a normally shaped gallbladder with thin walls and no signs of gallstones present at the moment of examination. Before the CT scan result ruled out a possible malignant tumor with duodenal invasion, our hypothesis was related to a possible gallbladder neoplasm or cholangiocarcinoma taking in consideration the gender and the age of the patient. A common characteristic in patients with gallbladder cancer is the strong association with gallstones and cholelithiasis, multiparty or increased body mass index. Chronic inflammation of the gallbladder induced by large gallstone (2-3 cm) may be considered either the emerging point of the carcinogenic process or an associative risk, studies suggesting that prophylactic cholecystectomy is not to be recommended in asymptomatic patients (18). Although there is an elevated risk associated with large gallstones, gallbladder cancer may mimic the same symptomatology in elderly patients making the differential diagnosis to be complex even in the presence of advanced radiological imagining. The best treatment was decided by the surgical and radiological unit judging upon the age, comorbidities, and high-risk procedure in case of our patient.

According to the recent data from the literature in AAC, LC is a safe procedure and it is proven to decrees the hospitalization stay. LC performed in the acute onset still associate's high morbidity (up to 41 %) and mortality (up to 4.5 %) because of several comorbidities in elderly patients and anesthetic risk. It is preferred to delay the intervention for 6- 8 weeks and perform minimal risk procedure such as PC (19). PC may be considered a safe procedure in elderly patients with associated comorbidities and increased surgical risk. Is a radiological procedure that does not need a surgical unit, a percutaneous catheter is inserted in the gallbladder under radiological guidance in the calculous form of acute calculous cholecystitis it also gives the possibility of stone dissolution and extraction. A study made by Kierkegard et al included 56 patients who were undergoing this procedure revealed that in 80.4 % of them PC was a definitive treatment option (20). Other studies considered that in critic elderly patients with severe sepsis, PC is a time delay procedure until the LC can be performed (21). Judging upon the prognosis of other comorbidities, limited survival and low recurrence rate of AAC, PC with percutaneous drainage of the pericholecystic abscess is to be considered the optimal surgical treatment in this case.

CONCLUSIONS

Our case emphasizes the fact that AAC may present, especially in elderly patients, as a severe condition, with redoubtable complications, such as perforation, pericholecystic abscess and cholecystoenteric fistula. Clinical picture may not be typical, the diagnosis being either established after several investigations or only intraoperative. Complications might imply high mortality if left untreated, especially in elderly patients; in the same time, advanced age and comorbidities are reasons for which caution in using surgical therapeutic arsenal is required.

PROGNOSTIC VALUE OF PREOPERATIVE LYMPHOCYTE RATIO IN HOSPITALIZED GERIATRIC PATIENTS WITH EXTRACAPSULAR HIP FRACTURES: PRELIMINARY RESULTS (Abstract) Despite the development of modern implants and multidisciplinary approach to extracapsular proximal femoral fractures in the geriatric population, mortality remains high. Our aim is to identify the factors that influence the mortality of these patients to optimize their treatment. **Material and methods:** We analyzed for 12 months' geriatric patients with extracapsular fractures of the proximal femur in terms of age, sex, place of origin, type of fracture, treatment type, duration of preoperative interval variation of hematological values and in-hospital mortality. **Results:** We identified 262 geriatric patients with a mean age of 76.29 years ± 12.14. Sex ratio was 2/1 for the female patients. 7/224 (3.1%) of operated patients and 9/38 of functional treated patients (15.8%) died during hospitalization (p=0.005). The duration of preoperative interval ranged between 1 and 19 days, with no significant differences in the average recorded types of fractures (p=0.355). In the case of deceased patients, we noticed a slight decrease in lymphocytes count, while operated patients, recorded a slight increase (p=0.091). ROC curve showed the best predictability of the percent lymphocyte ratio for mortality (AUC=65%; IC95: 0,523-0,777). **Conclusions:** Preoperative lymphocyte ratio may be a prognostic factor for mortality during hospitalization of geriatric patients with extracapsular fractures of the proximal femur. **Keywords:** LYMPHOCYTE, HIP FRACTURE, MORTALITY, GERIATRIC, PROGNOSIS.

Trochanteric fractures represent a significant source of morbidity and mortality for geriatric population despite development of modern implants and multidisciplinary approach (1).

Despite numerous attempts to outline the factors influencing mortality during hospitalization, the results were inconclusive. Several factors were considered: patient age (2, 3), associated comorbidities (4) delay of surgery (5-7), hemoglobin level at admission (8), nutritional status (9-10). The purpose of the study was to determine the prognostic value of preoperative lymphocyte ratio for mortality during hospitalization for geriatric patients with extracapsular fractures of the proximal femur.

MATERIAL AND METHODS

We reviewed all consecutive geriatric patients with extracapsular fractures of the proximal femur, admitted to Orthopedic

Clinic of "Sf. Spiridon" County Clinical Emergency Hospital from Iasi between January and December 2015. We analyzed demographic characteristics of patients, type of fracture, type of treatment, preoperative interval, hematological profile at admittance and preoperative day and mortality during hospitalization.

Data were collected from patients' clinical observation sheets and by using Unique Integrated Information System (UIIS). A two-sided p - value of 0.05 was considered significant for all tests. All analyses were conducted using *SPSS 21.0* (SPSS, Inc., Chicago, IL, USA).

RESULTS

We identified 262 geriatric patients with a mean age of 76.29 ± 12.14 years. The gender distribution highlights the increased number of female patients (66.4%), sex ratio is 2/1; 88.5% of basicervical fractures, 78.6% of complex trochanteric fractures, 65.6% of fractures pertrochanteric and 63.6% of trohantero-diaphyseal fractures were women, while in males prevails avulsion fractures of the trochanter (54.5%) and intertrochanteric fractures (53.8%) (p=0.05). 57.1% of patients were from rural areas.

In this study group, 85.5% of patients were operated and 14.5% received functional treatment; 7/224 (3.1%) patients operated and 9/38 patients treated functionally (15.8%) died during hospitalization (p=0.005) (fig. 1, 2).

Among deceased patients during hospitalization (n=13), 69,5% were pertrochanteric fractures and 30,8% basicervical fractures (p=0,035).

Distribution of cases by age showed no significant differences depending on the type of treatment used and the evolution during hospitalization (p=0.551).

Operated patients were more frequently engaged in age groups 70-79 years (29.5%) and 80-89 years (41.1%).

Among patients with functional treatment, 39.5% were aged 80-89 years. Most deaths were noted in patients aged 80-89 years (61.5%) (fig. 3, 4).

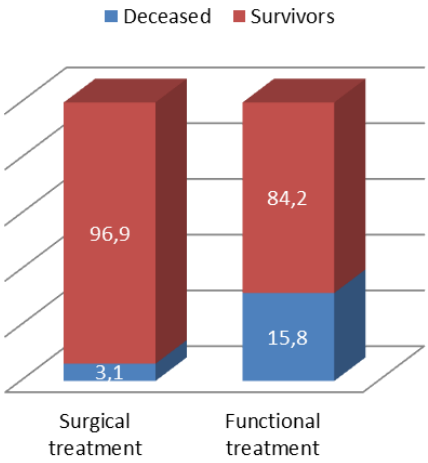

Fig. 1. The percentage of survival according to type of treatment

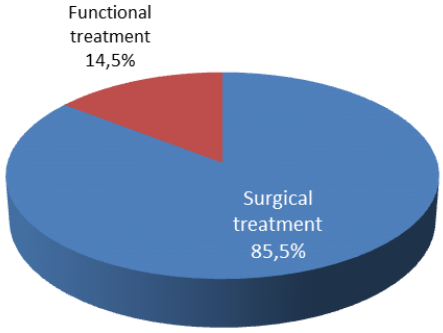

Fig. 2. Type of treatment in the cohort

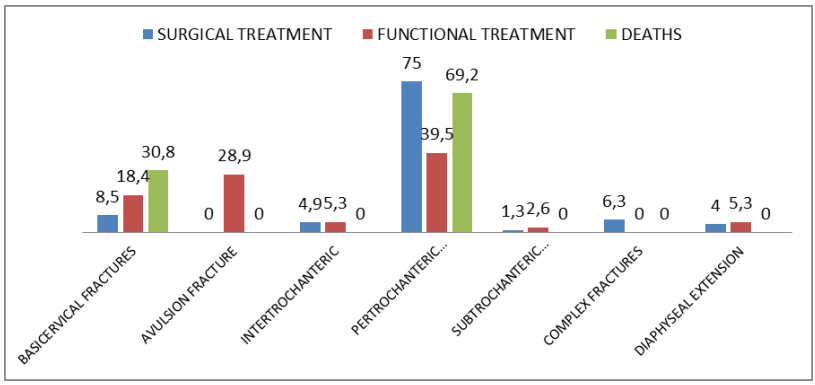

Fig. 3. The correlation between the type of fracture, the method of treatment and death

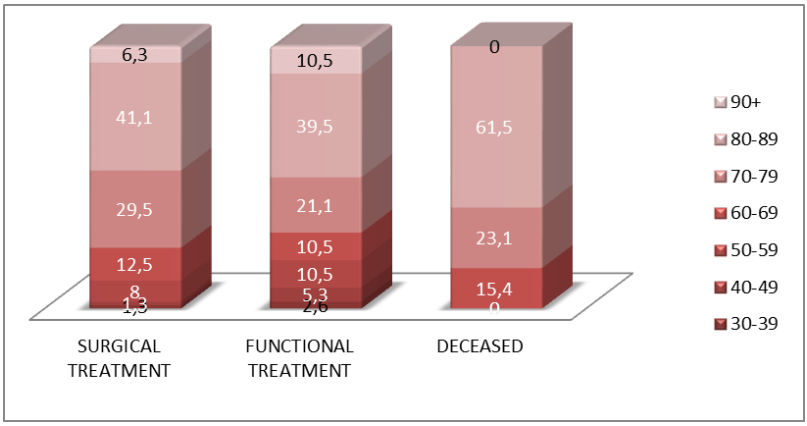

Fig. 4. Distribution of cases by age, type of treatment and survival

Pre-op interval ranged from 1 to 19 days, with no significant differences between types of fractures (p=0.355): the highest average value was found in 9 patients with fractures diaphyseal extension (6, 56 ± 4.19 days). The lowest preoperative interval was found in patients with intertrochanteric fractures (3.73 ± 1.56 days).

Variation of hematological values was not statistically significant for the deceased patients except lymphocytes ratio.

Although the number of lymphocytes at the time of operation recorded an average grown compared to admission, the differences were not significant (1.27 *vs.*1.81; p=0.143) (fig. 5).

During hospitalization, patients with functional treatment recorded decrease of the percentage of lymphocytes by an average of about 11 units, while patients operated recorded decrease about 10 units. Deceased patients have registered a decrease by 7 units (p=0.463).

In patients with functional treatment and deceased we observed a slight decrease in lymphocytes count and a slight increase in operated patients (p=0.091) (fig. 6)

ROC curve highlights the best predictability of lymphocite ratio for mortality (AUC=65%; CI95: .523-.777). The remaining parameters do not provide statistically acceptable predictability (AUC<0.600) (fig.7).

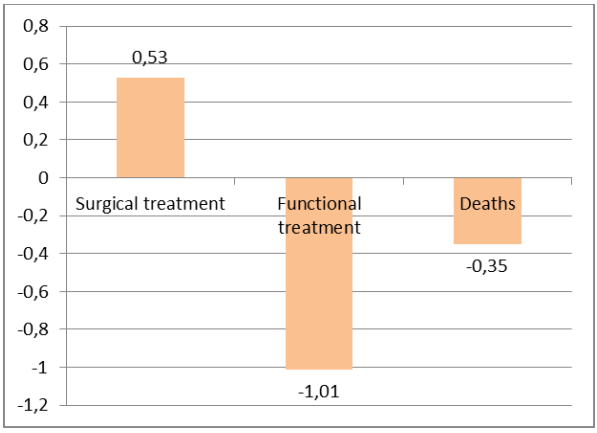

Fig. 6. The average level of lymphocyte per the method of treatment and survival

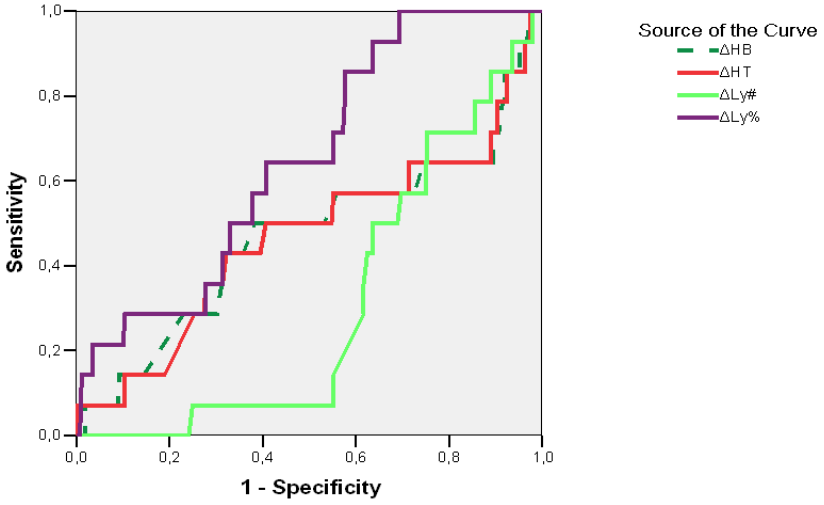

Fig. 7. The ROC Curve

DISCUSSION

This study analyzes the factors that influence hospital mortality of geriatric patients with extracapsular fractures of the proximal femur.

Our results regarding the influence of gender on mortality were in discrepancy with the literature (1-4, 11-12): we have noticed an increased mortality among female patients.

Influence of preoperative interval on mortality is a controversial topic, results of studies being discrepancy (5-7). In our study, we did not find a link between mortality and duration of preoperative interval and we recommend appropriate preoperative detrimental to surgery in the first 24 hours.

Our results regarding the influence of lymphocytes count on mortality, although inconclusive, confirmed results described by Kumar (9), among deceased patients were recorded lower values of lymphocytes with about 7 units (p=0.463). Lymphocyte ration was a significant predictor for mortality within hospital stay.

CONCLUSIONS

Present study demonstrates the prognostic value of the variation of lymphocytes percentage in assessing the risk of death during hospitalization geriatric patients with extracapsular fractures of the hip.

DETECTION OF AMINOGLYCOSIDE AND MACROLIDE RESISTANCE MECHANISMS IN METHICILLIN-RESISTANT *STAPHYLOCOCCUS AUREUS* (Abstract): Methicillin-resistant *Staphylococcus aureus* can become resistant to many different classes of antibiotics. **Objective:** To characterize aminoglycoside and macrolide resistance mechanisms in MRSA strains in relation to antibiotic susceptibility patterns. **Materials and methods:** We tested 86 MRSA strains using multiplex PCR for detection of genes *mecA, aac(6')-Ie/aph(2"), ant(4')-Ia, aph(3')-IIIa, ermA, ermC and msrA.* **Results:** There was a prevalence of *msrA* (32.5%), *ermC* (30.2%) and *aph(3')-IIIa* (61.6%) genes, which are less frequently reported in MRSA. Most *msrA* genes was detected in PVL positive strains (92.8%) and was associated only with non-MDR strains, while *ermC* genes were associated with MDR strains. PVL producing strains were characterized by the presence of *aph(3')-IIIa* (93.1%) and *msrA* genes (93.1%), being phenotypically susceptible to clindamycin. **Conclusions:** Detection of aminoglycoside and macrolide resistance genes allowed us to establish the concordance between genotypic and phenotypic methods and to correlate the presence of certain resistance genes with the type of circulating strain and the production of virulence factors. **Keywords**: MRSA, MULTIPLEX PCR, AMINOGLYCOSIDE, MACROLIDE.

Methicillin-resistant *Staphylococcus aureus* (MRSA) is one of the most common nosocomial pathogens, responsible for a broad spectrum of infections, which can become resistant to different classes of antibiotics. Aminoglycosides play an important role in the treatment of staphylococcal infections (1). There are several mechanisms for aminoglycoside resistance, the most frequent being inactivation by enzymatic modification that involves over 50 enzymes and multiple phenotypes (2). The genes encoding for those enzymes are usually found on plasmids and transposons. The majority of aminoglycoside modifying enzymes seen in MRSA strains are encoded by genes *aac(6')-Ie/aph (2"), ant(4')-Ia* and *aph(3')-IIIa* (2, 3). Resistance to gentamicin, kanamycin, and tobramycin is mediated by a bi-functional enzyme displaying acetyltransferase *aac(6')* and phosphotransferase *aph(2")* activity. The adenyltransferase *ant(4')-Ia* inactivates neomycin, kanamycin, tobramycin and amikacin, while the

phosphotransferase *aph(3')-III* inactivates neomycin (1, 2). Susceptibility testing against a range of aminoglycosides can help establish the resistance patterns that are unique for each enzyme (4).

Macrolide resistance in *S. aureus* can be caused by altered ribosomal target, active efflux or antibiotic inactivation. The most common mechanism is target modification mediated by one or more erythromycin ribosome methylase (*erm*) genes that confer resistance to macrolide, lincosamide, and streptogramin B (MLS_B phenotype) (5). The macrolide streptogramin resistance (*msr*) drug efflux mechanism causes the MS_B phenotype (5, 6).

Given the frequent association of methicillin resistance with multiple resistance to other non-beta-lactam antibiotics, in this study we aimed to implement, for the first time in the Microbiology Laboratory of UMPh "Grigore T. Popa" Iasi, a multiplex PCR assay for identification of MRSA strains resistant to aminoglycosides and macrolides, in order to describe the resistance mechanisms in relation to the antibiotic susceptibility patterns of MRSA strains.

MATERIAL AND METHODS.

We have tested 86 community-acquired (CA-MRSA) and hospital-associated (HA-MRSA) isolates from "St Parascheva" Clinical Infectious Diseases Hospital, Iaşi, collected from localized and systemic infections during a 3 year' period (2008-2010) and previously tested for *lukF/S-PV* genes encoding Panton Valentine leukocidin (PVL) (7). In this study, we performed three multiplex PCR reactions, each at a total volume of 50 µL, using 5 µL of template DNA, *ImmoMix*^{TM}*Red Master Mix* (*Bioline, UK*), primers at 50 pmol/reaction (*Metabion international*, Germany) selected from the DNA sequences previously published (8-12**).** Amplification was performed using *Corbett Palm-Cycler* (*Qiagen*, USA) under thermal cycling conditions described in tab.I and analysis was done by electrophoresis in 2% agarose gel, at 130V, for 35 minutes. In addition to PCR tests, phenotypic methods were also used as previously described (7) and antimicrobial susceptibility patterns were evaluated.

RESULTS

The results of aminoglycoside and macrolide resistance genes are presented in tab. II. The most common macrolide resistance gene was *msrA* (32.55%), associated only with non-multidrug resistant (MDR) strains. Phenotypically, 26 of 28 of those strains were resistant to erythromycin. Particular for those strains was the association with PVL toxin production (26/28). All erythromycin–resistant PVL positive strains carried only *msrA* gene, being phenotypically susceptible to clindamycin. During the study we have observed a significant increase in the proportion of the strains carrying *msrA* gene from one year to another (p = 0.02) and a significant decrease in the proportion of the strains carrying *ermA* gene (p = 0.01). *ErmA* and *ermC* genes were detected in equal proportions (30.23%) and were associated with MDR strains. All *ermC* strains were phenotypically resistant to erythromycin and the majority (25/26) were resistant to clindamycin. Twenty of the 26 *ermA* positive strains were phenotypically resistant to erythromycin and only half were resistant to clindamycin. Macrolide resistance genes were also detected in strains phenotypically susceptible to erythromycin (3 strains showed *ermA* gene and 2 strains were carrying *msrA* gene). We have observed a significant association of *ermA* gene with HA-MRSA strains (the gene was present in 60% of HA-MRSA strains and in only 22.58% of CA-MRSA strains, p=0.001), while in contrast, *msrA* genes were associated with CA-MRSA isolates (23/28 *msrA* positive strains, p=0.008). Detection of macrolide resistance genes showed a concordance between phenotypic and genotypic methods of 94.18% for erythromycin and 82.55% in case of clindamycin. The sensitivity of phenotypic detection of resistance to erythromycin was 91.25% and lower for clindamycin (73.07%).

Of the total MRSA isolates, 6 (6.97%) were negative for aminoglycoside resistance genes and carried PVL genes. The most frequent aminoglycoside resistance gene was *aph(3')-IIIa* (61.62%). This gene was the only one associated with PVL producing strains (93.1%, p<0.001). Genes *aac(6')-Ie/aph(2")* were present in 27.9% of strains, while gene *ant (4')-Ia* in only 3.4% of strains. Genes *aac(6')-Ie/aph(2")* and *ant(4')-Ia* were associated with MDR strains, while gene *aph(3')–IIIa* was found both in MDR and in non-MDR strains. In one case, the strain was resistant to gentamicin phenotypically, but none of the 3 genes was present, suggesting the involvement of another mechanism of resistance. Also, in one case, the gene *aac(6')-Ie/aph(2")* was detected in a strain with phenotypic susceptibility to gentamicin.

TABLE II

Results for macrolide and aminoglycoside resistance genes detection

	Macrolide resistance				Aminoglycoside resistance			
Detected gene	*ermA*	*ermC*	*msrA*	Negative	*aph(3')*	*aac(6')/aph(2")*	*ant(4')*	Negative
No. of strains	26	26	28	6	53	24	3	6
PVL +	0	0	26	3	27	0	0	2

DISCUSSION

The presence of resistance genes can be correlated with data on antibiotic resistance profiles of CA-MRSA, HA-MRSA and PVL producing strains and can be used to adjust the application of therapeutic regimens in our region. This study reveals that *ermA* gene was more commonly found in HA-MRSA (60%) strains, data consistent with those described by Pruneau *et al.* and Sun *et al*. (13, 14). Contrary to reports of *ermA* gene being the dominant *erm* gene in *S. aureus*, our results showed the same proportion for *ermA* and *ermC* genes. No combination of *ermA* and *ermC* was detected. Per Sun *et al*., *ermA* gene was frequently detected in HA-MRSA isolates (86.9%) while the detection rates of *ermB* and *ermC* genes were lower, and the mentioned study also revealed the triple combination of *ermA, ermB* and *ermC* in 17.8% of HA-MRSA isolates (14). In a study by Schmitz *et al*. the *ermA* gene was more common in MRSA isolates (88%) than MSSA (38%), and occurred mainly in strains with constitutive MLSB expression, while *ermC* was more common in MSSA (47%) than in MRSA (5%), occurring mainly in strains with inducible expression (5). Another particularity of tested strains was the high percentage of MRSA strains harboring *msrA* gene, mainly in CA-MRSA isolates. Contrary to our findings, Sun *et al* reported that CA-MRSA isolates only possessed the *ermA* gene (14) and Schmitz *et al.* detected the *msr* genes only in MSSA isolates (13%) (5). Similarly, Shittu *et al.* identified the *ermA* gene in all erythromycin-resistant MRSA isolates, while *msrA* gene was detected in MSSA isolates (15). Since isolates with MS_B phenotype are susceptible to lincosamides and 16-membered ring macrolides, detecting resistance genes is useful for timely and appropriate choice of antibiotics (16). Three MRSA isolates were susceptible to erythromycin even though they possessed the *ermA* gene. Similar discordance was found by Sun *et al* who stated that this could be caused by mutation in the coding or promoter region of the genes (14). Wong *et al* also reports the case of an erythromycin- and clindamycin-susceptible phenotype in an *ermA* positive strain and discovered, through DNA sequence analysis, a 48-bp deletion in Tn554 harboring *ermA* (6). In our study, there was no strain resistant to erythromycin that did not possess resistance genes. However, such cases were reported by Sun *et al*, when resistance genes were located on small plasmids, occasionally lost (14).

Interestingly, the most frequently identified gene implicated in aminoglycoside resistance in our study was *aph(3')-IIIa* (61.62%). This gene is infrequently found in *S. aureus*. Sun *et al* reported the presence of

this gene in 5.6% of HA-MRSA and no CA-MRSA isolates (14). Gene *ant (4')-Ia* is rarely detected in MRSA strains and this is in accordance with our findings (3.48%). Thus, Sun *et al*, detected *ant(4')-I* gene in 9.1% of CA-MRSA isolates (14). In our study, gene *aac(6')-Ie/aph(2'')*, frequently reported as predominant, was present in only 27.9% of isolates. Contrary to our findings, Sun *et al* reported that the most common aminoglycosides resistance gene was *aac(6')-aph(2'')*, which was found in 95.3% of HA-MRSA and 45.5% of CA-MRSA (14). Rahimi *et al.* also found a predominance of *aac(6')-aph(2'')* gene (65.6%) (1).

CONCLUSIONS

Characterization of macrolide and aminoglycoside resistance mechanisms revealed the particularities of MRSA strains in our region. The isolates showed a high prevalence of *msrA*, *ermC* and *aph(3')-IIIa* genes, which are less frequently reported in MRSA. The majority of *msrA* genes was detected in PVL positive strains (92.8%) and was associated only with non-MDR strains, while *ermC* genes were associated with MDR strains and phenotypic resistance to clindamycin (92.3%). PVL producing strains were characterized by the presence of only *msrA* genes (being phenotypically susceptible to clindamycin) (93.1%) and *aph(3')-IIIa* (93.1%).

Multiplex PCR techniques for detection of genes encoding resistance factors in MRSA isolates permit rapid identification of strains with associated resistance to non-beta lactam antibiotics and may improve diagnosis and help adjust therapeutic regimens and preventive measures.

NEWS

GENETIC SUSCEPTIBILITY TO INSULIN RESISTANCE ASSOCIATED WITH LOWER ADIPOSITY

The researchers tried to demonstrate the relationship between adiposity, genetic susceptibility to insulin resistance or insulin secretion and the response to GH treatment in short children born small for gestational age(SGA).The study was realised on 89 short prepubertal SGA children treated with GH for one year in a multicentre study. Combined multiallele gene scores based on single nucleotide polymorphisms with known associations with lower insulin sensitivity and insulin secretion were analysed. The results showed that during GH treatment, GS-In Res was related to a lesser decline in trunk fat and a higher trunk- limb fat ratio at 1 –year. GS-In Sec was positively associated with truncal fat (Thankamony A[1,2], Jensen RB[1], O'Connell SM[3] et al. Adiposity in children born small for gestational age is associated with β-cell function, genetic variants for insulin resistance and response to growth hormone treatment. *J Clin Endocrinol Metab.* 2015 Nov 20: jc20153019).

SIMULTANEOUS UNILATERAL RADIAL SHAFT FRACTURE WITH DISTAL AND PROXIMAL RADIOULNAR JOINT DISLOCATION, AN EXTREMELY RARE CASE REPORT

Mani Falsafi, Behnam Baghianimoghadam
University of Medical Sciences, Babol, Iran
Department of Orthopedic Surgery

SIMULTANEOUS UNILATERAL RADIAL SHAFT FRACTURE WITH DISTAL AND PROXIMAL RADIOULNAR JOINT DISLOCATION, AN EXTREMELY RARE CASE REPORT (Abstract): Till now we know two fracture pattern in forearm fracture dislocation, Galeazzi fracture dislocation which is defined as fracture of radial shaft with distal radioulnar joint (DRUJ) dislocation and Monteggia fracture dislocation which is ulnar fracture with radial head dislocation. During this case report we present a case with simultaneous distal and proximal radioulnar dislocation and radial shaft fracture which is extremely rare fracture pattern and could be a new entity in forearm bones fracture dislocation. **Keywords**: RADIAL SHAFT FRACTURE, RADIAL HEAD, DISTAL RADIO ULNAR JOINT (DRUJ)

The fracture of radial shaft simultaneously with proximal and distal radioulnar joint dislocation in an extremely rare event in children and adults. This pattern doesn't conform to Galeazzi, Monteggia and Essex-Lopresti fractures (1-3). We did not found any other similar cases during our search. During this case report we present a case with simultaneous distal and proximal radioulnar dislocation and radial shaft fracture

CASE REPORT

A 52 years old man admitted in our emergency ward after a motor vehicle accident. The patient was motorcycle rider and had a crash with a car. There was sever pain and restriction in range of motion in both right wrist and elbow joint. Also patient had a severe pain and deformity in right forearm. Supination and pronation in elbow and wrist were absent. Also flexion and extension in both joint were painful.

In plain radiography a radial shaft fracture, anterolateral dislocation of radial head and dorsal dislocation of ulnar head with mild ulnar plus was apparent. No other fracture was determined (fig. 1).

Patient was transferred to operation room and open reduction with Dynamic compression plate was done, the elbow joint was checked with fluoroscopy which was reduced after radial shaft fixation. Then a long arm cast in neutral flexion of elbow and forearm supination was applied (fig. 2). A long arm cast was applied in supination of forearm and neutral position of elbow. The post-operative radiographies were acceptable. After four weeks the cast was removed and physiotherapy started. Radiographs were taken at 3rd, 6th and 12th weeks and then at 3 monthly intervals until 10 months.

The fracture was united and patient was able to 80° extensions and 75° flexion at wrist, 80° of supination and pronation at the fore-arm during 12th week visit.

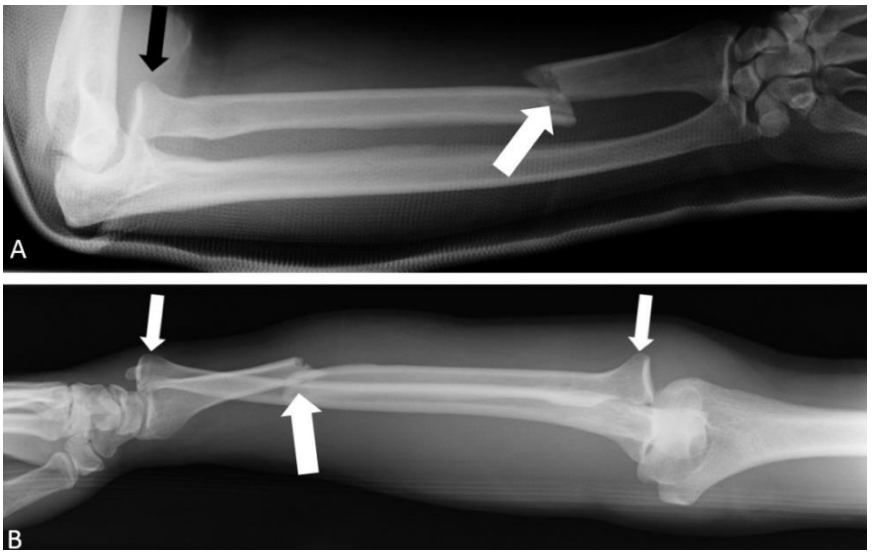

Fig. 1. Pre-operative lateral (A) and Anteroposterior (B) x-rays. The dislocation of distal and proximal radioulnar joints (arrows) and the radial shaft fracture are apparent.

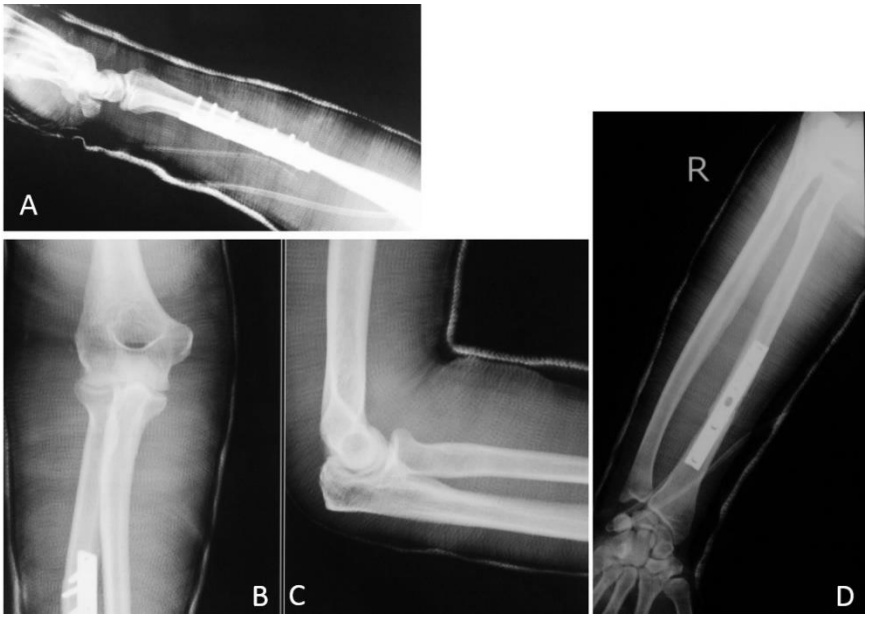

Fig. 2. Post-operative x-rays. Lateral (A) and anteroposterior (D) X-rays of distal radioulnar joint (DRUJ) and lateral (C) and anteroposterior (D) X-rays of elbow joint. The radial shaft is fixed with 3.5 DCP plate, distal and radioulnar joint are reduced.

DISCUSSION

During this case report we presented a patient with dislocated distal and proximal radioulnar joint simultaneously with radial shaft fracture. This pattern was not reported in any previous case reports. Distal radioulnar joint dislocation often is associated with unstable radial fracture which was firstly described by cooper in 1822 and named as Galeazzi fracture-dislocation after Ricardo Galeazzi's presentation case series in 1934 (1). Also isolated radial head dislocation is associated with proximal ulnar fracture which was described by Giovanni Battista Monteggia, in 1814 (2). The Essex-Lopresti injury is characterized by a fracture of the radial head with concomitant disruption of the distal radioulnar joint (DRUJ) and rupture of the interosseous membrane (IOM) (3).

There are few case reports on simultaneous dislocation of proximal and distal radioulnar joint (4-9). In these cases, there are either pure dislocation of distal and proximal radioulnar joints (4, 6-9) or simultaneously with elbow dislocation or radial head fracture (5). But there is no report on proximal and distal radioulnar joint dislocation with radial shaft fracture (10-13). This case is the first report of such a fracture pattern.

It seems that hyper pronation is the causative force for the simultaneous dislocation of proximal and distal radioulnar joint. When the patient falls onto dorsiflexed wrist, pronated forearm and extended elbow, he might rotate the body over the affected limb which is fixed to ground. This rotation can cause much pronation that can disrupt triangular fibrocartilage complex and also varus force that cause disruption of annular ligament. But fracture of radial shaft during each stage of this process can interfere the described mechanism and prevent to dislocate the proximal or distal radioulnar joints. In our case the fracture of radial shaft was fixed with Dynamic Compression Plate. The radial and ulnar head were reduced after plating of radial shaft. A long arm cast was applied in supination of forearm and neutral position of elbow. The post-operative radiographies were acceptable and final outcomes was favorable during follow-ups.

BIOLOGICS IN RHEUMATOLOGY: BRITISH GUIDE UPDATE

On August 24th, in *Rheumatology*, the British Society for Rheumatology (BSR) and British Health Professionals in Rheumatology (BHPR) Standards, Guidelines and Audit Working Group published an updated guideline for prescribing biologics to the patients with axial spondyloarthritis (including Ankylosing Spondylitis). The group recommended the inclusion in biological therapy not only patients with Ankylosing Spondylitis meeting the modified New York criteria, but also those with non-radiographic disease, but only in cases with real evidence of inflammation on MRI or a raised C-reactive protein. Also, they advised the clinicians to switch from one TNF- inhibitor to another anytime during the treatment, reducing the time between BASDAI measurments to 4 weeks. Regarding the problem of choosing one TNF-inhibitor or another for axial spondyloarthritis, the studies the group reviewed did not demonstrate an important difference in terms of efficacy between infliximab, golimumab, etanercept, certolizumab and adalimumab. Response evaluation of the treatment in patients with TNF-inhibitors should be realised every 3 to 6 months, and the responsive ones must be reassessed every 6 months after. It is important to acknowledge that the non- responsive patients (those with no clinical response by 6 months or if the response is not maintained at two consecutive assessments) should be discontinued. The working group did not answered though to an important issue, if the anti-TNF therapy could prevent radiographic progression or not. (Hamilton L, Barkham N, Bhalla A et al. BSR and BHPR guideline for the treatment of axial spondyloarthritis (including ankylosing spondylitis) with biologics. *Rheumatology.* 2016 . doi:10.1093/rheumatology/kew223.233-6)

IMMUNOHISTOCHEMISTRY IN ENDOMETRIAL HYPERPLASIA AND ENDOMETRIAL ADENOCARCINOMA (Abstract) **Aim**: Endometrial hyperplasia is a proliferation of endometrial glands due to the prolonged stimulation with estrogens of the endometrium that occurs in women receiving exogenous estrogens, with anovulatory cycles, or in patients with ovarian tumours with estrogen secretion. **Material and methods**: The study performed by the authors included 575 patients with endometrial hyperplasia and 163 patients with endometrial adenocarcinoma admitted to the "Cuza-Vodă" Obstetrics and Gynaecology Clinical Hospital of Iasi, between 2005-2007. **Results**: There were selected, for these immunohistochemistry reactions, 22 cases of simple hyperplasia without atypia, 26 cases of complex hyperplasia without atypia, 23 cases of endometrial adenocarcinoma of endometrioid type, well differentiated, 22 cases of endometrial adenocarcinoma of endometrioid type, moderately differentiated, and 19 cases of non-endometrioid adenocarcinomas represented by nine clear cells and 10 serous endometrial adenocarcinomas. Estrogen receptors have been positive in about 85-90% of the tumour cells of the well-differentiated endometrial adenocarcinomas of endometrioid type (GI). In endometrioid-type endometrial adenocarcinomas moderately differentiated (GII), the estrogen receptors were positive in approximately 70-85% of the tumour cells. **Conclusions**: Endometrial hyperplasia, especially complex endometrial hyperplasia with atypia, increase the risk for endometrial adenocarcinoma, and their early detection becomes mandatory under cancer prevention. Well-differentiated endometrioid endometrial adenocarcinomas were ER and PR-positive, so that the ER expression correlated with the PR expression. Well-differentiated endometrioid endometrial adenocarcinomas (GI) in the studied group also showed a higher content of ER and PR compared to the endometrial moderately-differentiated endometrioid endometrial adenocarcinomas (GII). In non-endometrioid adenocarcinomas, represented by clear-cell endometrial adenocarcinomas, the ER content was reduced and the PR expression was negative. Serous adenocarcinomas failed to show an immunohistochemically expression for ER and PR. **Keywords**: IMUNOHISTOCHEMITRY, ADENOCARCINOMA, ENDOMETRIUM.

The link between endometrial hyperplasia and endometrial carcinoma was mentioned in several studies. Some of them have shown a development of the endometrial carcinoma in 2% of the complex endometrial hyperplasia without atypia and

20-30% of the complex atypical hyperplasia, therefore the complex atypical hyperplasia is a precursor of endometrial carcinoma (1).

Pesce and al. (1) describe two subtypes of endometrioid adenocarcinoma, represented by adenocarcinoma with trophoblastic differentiation and adenocarcinoma with Sertoli form differentiation. The endometrioid adenocarcinoma with trophoblastic differentiation has giant multinucleated cells, of the syncytiotrophoblastic type, that are immunoreactive to HGG, while the cells of the endometrioid adenocarcinoma with Sertoli form differentiation are similar to the ovarian tumours with the same differentiation type.

The expression of PTEN (Phosphatase and tensin homologue deleted on chromosome ten) is an oncosupressor gene of the same class of p53, rbp and APC recently identified in the Cz 10q23 (LI) region, which encodes a protein with 403 amino acids, of the multifunctional phosphatase type, with a very wide tissue nuclear expression, which is involved in the regulation of the cell cycle and apoptosis. PTEN's tumour suppressor gene mutation has been reported in approximately 50-83% of endometrial adenocarcinoma.

PTEN is expressed in most human tissues. PTEN deletions and mutations occur not only in endometrial carcinomas but also in glioblastoma, prostate carcinoma, lung carcinoma and mammary carcinoma, and it is mostly associated with invasiveness.

PTEN inactivation in endometrioid adenocarcinomas and in many other types of tumors cannot be explained only on the basis of the observed mutations. This observation suggests that the expression of PTEN is suppressed at transcriptional and translational level through other mechanisms (12).

With the help of the immunohistochemically evaluation of the estrogens (ER) and progesterone (PR) it is better appreciated their distribution in tumour tissues and normal peritumoral tissues. In endometrial carcinoma, the ER/PR status, in particular PR, correlate with histological differentiation and survival. In well-differentiated carcinoma, the ER/PR positivity is more common and it is associated with a better prognosis. It is believed that an ER/PR positive endometrial carcinoma responds better to hormonal therapy (9).

Cyclooxygenases COX-1 and COX-2 are enzymes which play an important role in the synthesis of prostaglandins from the arachidonic acid. COX-2 expression has been related to carcinogenesis and the COX-2 specific inhibitors that have antitumour effects. The immunohistochemically expression of COX-2 has been reported in a variety of normal and neoplastic tissues.

Her-2/neu/cerbB2 oncogene is part of the EGFR genes family. The detection of Her-2/neu in gynaecological tumours is important, both as a prognostic marker and also to qualify the Herceptin therapy. The normal endometrial glands are weakly to moderately positive for Her-2/neu. Compared with normal endometrium, 9% of the endometrial adenocarcinoma demonstrate a stronger positivity for Her-2/neu.

Ki-67 is a nuclear factor of the cellular proliferation, with protein structure with two isoforms.

P53 is a tumour suppressor gene, located on the short arm of chromosome 17. P53 is most frequently positive in the papillary serous adenocarcinoma and also in other carcinomas with poor prognosis, with a high degree of malignancy and high prolif-

eration index (2).

K-ras oncogene mutations have been detected in 10-25% of endometrial carcinomas and 17% of the atypical hyperplasia (3). K-ras activation is an early event in the carcinogenesis of endometrial carcinoma. Studies have shown that K-ras oncogene is an independent negative prognostic factor (4).

MATERIAL AND METHODS

The study included 575 patients with endometrial hyperplasia and 163 patients with endometrial adenocarcinoma admitted to the "Cuza-Vodă" Obstetrics and Gynaecology Clinical Hospital of Iasi, between 2005-2007.

The collection, processing and interpretation of the information required for the clinical-statistical study on knowing the peculiarities of the cases were performed using data recorded in the case report forms and in the computer system.

The immunohistochemistry reactions performed on the cases in the hyperplasia and endometrial adenocarcinoma group in our study had in view the assessment of the hormone receptors for estrogen (ER) and progesterone (PR), the PTEN gene protein, the Her2/neu (cerb-2)/ gene protein, the nuclear factor of Ki-67 cell proliferation, cyclooxygenase 2 (COX-2), metalloproteinases (MMP-2 and MMP-9).

The data used as study material from the patient charts refer to the division of cases into age groups, their distribution according to their residence environments, according to their profession, to their admission reasons, to personal physiological history, to personal pathological history, and to family history relevant for endometrial carcinoma.

The age of patients with endometrial carcinoma is an important prognosis factor independent from other parameters. In our study, the patients with endometrial carcinoma were aged 30 to 70, with an average age of 58.94 years. The highest percent – 29.3% - are patients over 65 years old. The percent of patients younger than 50 was 6.84% of the cases. The socioeconomic status can be perceived as a risk in developing endometrial adenocarcinoma, as well as a condition for the increase in the rate of women who submit to specialty consultation, due to a high education level enabled precisely by their high standard of living. Moreover, the low socioeconomic level is a factor affecting negatively the subsequent monitoring of patients who can develop endometrial adenocarcinomas.

RESULTS

There were selected, for these immunohistochemistry reactions, 22 (3,82%) of simple hyperplasia without atypia, 26 (4,52%) of complex hyperplasia without atypia, 23 (4%) of endometrial adenocarcinoma of endometrioid type, well differentiated, 22 (3,82) of endometrial adenocarcinoma of endometrioid type, moderately differentiated, and 19 (3,3%) of non-endometrioid adenocarcinomas represented by nine clear cells and 10 (1,74%) serous endometrial adenocarcinomas.

Estrogen receptors were present in different percentages in the studied hyperplasia and endometrial adenocarcinomas (table I). The marking recognized amount is represented by the nuclear marking.

In simple endometrial hyperplasia without atypia, estrogen receptors were positive in 85-95% of the glandular epithelial cells. In complex endometrial hyperplasia without atypia, the estrogen receptors were positive in 70-90% of the glandular epithe-

lial cells.

Estrogen receptors have been positive in about 85-90% of the tumour cells of the well-differentiated endometrial adenocarcinomas of endometrioid type (GI). In endometrioid-type endometrial adenocarcinomas moderately differentiated (GII), the estrogen receptors were positive in approximately 70-85% of the tumour cells. The estrogen receptors in clear-cell endometrial adenocarcinomas were positive in 40-45% of the tumour cells. In serous endometrial adenocarcinomas, the estrogenic receptors were negative in the tumour cells and they showed positivity only in the remaining glandular epithelium (table I).

TABLE I.

Results of the study of ER and PR hormone receptors

Histological type		No. Cases	ER %	PR %
Endometrial hyperplasia	Simple hyperplasia without atypia	22	85-95	85-95 %
	Complex hyperplasia without atypia	26	70-90	80-90
Endometrioid ADK	Well-differentiated endometrioid ADK (GI)	23	85-90	90-95
	Moderately-differentiated endometrioid ADK (GII)	22	70-85	80-85
Non-Endometrioid ADK	Clear-cell endometrial ADK	9	40-45	0
	Serous cells endometrial ADK	10	0	0

The cases of simple endometrial hyperplasia without atypia expressed progesterone receptors in 85-95% of the glandular epithelial cells. In complex endometrial hyperplasia without atypia, the progesterone receptors were positive in 80-90 % of the glandular epithelial cells.

Progesterone receptors were positive in 90-95 % of the tumour cells of the well-differentiated endometrial adenocarcinomas of endometrioid type (GI).

In endometrioid-type endometrial adenocarcinomas moderately differentiated (GII), the progesterone receptors were positive in 80-85 % of the tumor cells.

In serous endometrial adenocarcinomas, the progesterone receptors were negative in the tumour cells and they showed positivity only in the remaining glandular epithelium.

The progesterone receptors were negative in clear-cell endometrial adenocarcinomas and they were positive only in the remaining glandular epithelium (table I).

In simple hyperplasia and complex hyperplasia without atypia, PTEN showed regional positivity in the glandular epithelial cells. The reaction was negative in a single case of complex hyperplasia without atypia. PTEN showed regional positivity in the tumour cells of the endometrial adenocarcinoma tumor of endometrioid type, well differentiated (GI) and moderately differentiated (GII).

In serous endometrial adenocarcinomas, PTEN gene protein was positive in rare tumor cells and diffusely positive in the remaining glandular epithelium.

The PTEN gene protein was regionally positive in the tumour cells of the clear-cell endometrial adenocarcinomas.

In terms of the immunohistochemical expression of C-erbB2 (Her2/neu/cerb-2 gene protein), in endometrial adenocarcinomas of endometrioid type and in clear-cell endometrial adenocarcinomas of our lot, the reaction to cerb-2 was negative. In serous endometrial adenocarcinomas, cerb-2 showed regional positivity in tumor cells, scored with 2+.

The positivity of Ki-67 reaction was approximately 2-15% of the glandular epithelial cells in the simple endometrial hyperplasia without atypia. In complex endometrial hyperplasia without atypia, Ki-67 was positive in about 3-10 % of the glandular cells. Ki-67 was positive in about 25-30% of the tumour cells of the well-differentiated endometrial adenocarcinomas of endometrioid type (GI). In endometrioid-type endometrial adenocarcinomas moderately differentiated (GII), Ki-67 was positive in approximately 20-40 % of the tumor cells. Ki-67 was positive in about 60-65% of the tumor cells in the clear-cell adenocarcinomas. In serous endometrial adenocarcinomas, Ki-67 was positive in about 50-60 % of the tumour cells.

In simple endometrial hyperplasia without atypia, COX-2 is variably expressed in glandular epithelial cells from weak regional positivity to diffuse positivity. COX-2 shows a weakly positive regional reaction in the glandular epithelial cells of the complex endometrial hyperplasia without atypia. In the well-differentiated endometrial adenocarcinoma of the endometrioid type (GI) and moderately differentiated ones (GII), COX-2 is expressed diffusely in all the tumor cells. COX-2 is diffusely present in the cytoplasma of the tumour cells of the serous endometrial adenocarcinomas.

In simple endometrial hyperplasia without atypia, MMP-2 showed only in one case a weak positive reaction in the epithelial cells and a positive reaction in the stromal cells. In complex endometrial hyperplasia without atypia, MMP-2 showed only in one case a regional positive reaction in the epithelial cells and a regional positive reaction in the stromal cells. In well-differentiated endometrioid endometrial adenocarcinomas (GI) MMP-2 showed positive reaction in rare tumor cells and negative reaction in stromal cells. In moderately-differentiated endometrioid endometrial adenocarcinomas (G II), MMP-2 showed weak regional positive reaction in tumor cells only in one case and negative reaction in the stroma in all the cases. In serous endometrial adenocarcinomas, MMP-2 showed weak positive reaction in tumor cells and stromal cells. In clear-cell endometrial adenocarcinomas, MMP-2 has shown a negative reaction in both tumor cells and stroma.

MMP-9 showed a regional positive reaction in the epithelial cells and a regional positive reaction in stromal cells in simple endometrial hyperplasia without atypia. In complex endometrial hyperplasia without atypia, MMP-9 showed regional positive reaction in the epithelial cells and regional positive reaction in the stromal cells. In well-differentiated endometrioid endometrial adenocarcinomas (GI), MMP-9 showed regional positive reaction in the tumor cells and negative reaction in stromal cells. In moderately-differentiated endometrioid endometrial adenocarcinomas (GII), MMP-9 showed, in 2 cases, regional positive reaction in tumor cells and negative reaction in stromal cells in all cases. In one case it showed diffusely positive reaction in tumor cells and regional positive in stromal cells. MMP-9 showed a diffuse

positive reaction in tumour cells and stromal cells of serous endometrial adenocarcinomas. In clear-cell endometrial adenocarcinomas, MMP-9 showed weak positive reaction in tumor cells and stromal cells.

DISCUSSION

The completion of the histopathologic diagnosis in endometrial hyperplasias and adenocarcinomas with the immunohistochemical study has unquestionable value in assessing the prognosis of these lesions (13).

The results of the immunohistochemically study of ER and PR, PTEN, MMP-2, MMP-9, C-erbB-2, COX-2 and Ki 67 showed the value of these markers in differentiating the complex endometrial hyperplasia from the endometrioid adenocarcinomas.

The benign squamous metaplasia adenocarcinoma presents immunohistochemically positivity for ER and PR and it is rarely positive at Ki-67 and p53.

The malignant squamous metaplasia adenocarcinoma presents rare positivity for ER and PR and it is positive at Ki-67 and p53. No aspects of stromal invasion are identified at the serous intraepithelial carcinoma. In terms of immunohistochemistry, tumour cells are positive for Ki-67 and p53 and with focal positivity for ER and PR.

In our study, in simple and complex endometrial hyperplasia with no atypia, PTEN showed regional positivity in glandular epithelial cells, and in only one case of complex hyperplasia with no atypia the reaction was negative.

Both in the well-differentiated endometrioid endometrial adenocarcinomas (GI) and in the moderately differentiated adenocarcinomas (GII) in our cases, the expression of PTEN was regionally positive in tumour epithelial cells.

In weakly differentiated adenocarcinomas, represented by serous adenocarcinomas and clear-cell adenocarcinoma, the PTEN expression was weak.

In a study on the development of endometrial carcinomas, show that after various molecular alterations, represented by microsatellite instability and mutations of PTEN, K-ras and beta-catenin, the endometrial cells are transformed in endometrioid carcinoma, and the modification of the expression of p53 protein and the loss of LOH (loss of heterozygosity) on different chromosomes, leads to the development of endometrial non-endometrioid tumours (5).

PTEN is an early change that occurs in the pathogenesis of the endometrioid endometrial adenocarcinoma (6). These studies demonstrate that the immunohistochemically identification of PTEN protein is an important marker for endometrial premalignant lesions.

The PTEN mutations are important in the pathogenesis of the endometrioid endometrial adenocarcinoma. These mutations are shown in the normal mucosa, in postmenopausal women and in complex endometrial hyperplasia, aspects which suggest that PTEN mutations show an early change that occurs in the pathogenesis of the endometrioid endometrial adenocarcinoma (6). These studies demonstrate that the immunohistochemically identification of PTEN protein is an important marker for endometrial premalignant lesions (10).

Some authors (7) have demonstrated that the number of the progesterone receptors is dependent on the concentrations of estradiol and the progesterone in the serum. It was found that PR is more often positive in endometrial hyperplasia without atypia compared to the hyperplasia with atypia.

PR is expressed at a lower level in the endometrial carcinoma compared to the endometrial hyperplasia.

In endometrial carcinomas, the Her-2/neu positivity is correlated with ER negativity and it is associated more commonly with the existence of metastasis. This suggests that Her-2/neu positivity is associated with a much more aggressive evolution (8).

In our study, regional positivity scoring 2+ was found only in the serous endometrial adenocarcinoma, which is considered a weakly-differentiated carcinoma. In the clear-cell carcinomas and the endometrioid adenocarcinomas under study, the C-erb-2 reaction was negative.

In our cases, in endometrial hyperplasia, the MMP-2 and MMP-9 expressions were different, with a better expression of the MMP-9 than that of the MMP-2. MMP-9 showed regional expression in glandular epithelial cells and in stromal endometrial cells, both in simple hyperplasia with no atypia and in complex hyperplasia with no atypia. MMP-2 showed regional positivity in glandular epithelial cells only in 50% of simple and complex hyperplasia with no atypia, which was accompanied by a positive reaction in the endometrium stroma.

The antigenic profile of endometrial adenocarcinomas is different. The endometrioid adenocarcinoma is positive to ER and PR, negative to C-erb B-2 and it shows low positivity for Ki67. The non-endometrioid adenocarcinoma is negative to ER and PR, positive to C-erb B-2 and it shows a high Ki67 proliferation risk. The endometrioid adenocarcinoma is associated more frequently with PTEN mutations, compared to the non-endometrioid adenocarcinoma. In endometrial adenocarcinomas, MMP-9 is expressed more intensely than MMP-2 and it correlates with a low degree of differentiation of adenocarcinomas. In our study, COX-2 shows a positive diffuse reaction in most endometrial adenocarcinomas and in non-endometrioid adenocarcinomas (11).

In the endometrial hyperplasia of the cases under study, the expression of COX-2 showed a weak positive reaction regionally in glandular epithelial cells. An exception was a case of simple glandular hyperplasia with no atypia, in which the COX-2 was positive diffusively in glandular epithelial cells; this reaction can be explained by the patient's young age, correlated to her hormonal status (active genital period).

In all endometrial adenocarcinomas in our study, the COX-2 showed a positive reaction diffused in the tumoral cells, except for a case of endometrioid endometrial carcinoma GII, which showed a weak positive regional reaction.

In our cases, we noticed a positive correlation between the level of the Her-2/neu signal and the COX-2 expression in the serous endometrial carcinoma.

CONCLUSIONS

In our case studies, well-differentiated endometrioid endometrial adenocarcinomas (GI) and moderately differentiated (GII) ones had a relatively low content in the ER and PR of the tumor cells compared to the simple and complex hyperplasia without atypia. Well-differentiated endometrioid endometrial adenocarcinomas were ER and PR-positive, so that the ER expression correlated with the PR expression. Well-differentiated endometrioid endometrial adenocarcinomas (GI) in the studied group also showed a higher content of ER and PR compared to the endometrial moderately-differentiated endometrioid endometrial adenocarcinomas (GII).

In non-endometrioid adenocarcinomas,

represented by clear-cell endometrial adenocarcinomas, the ER content was reduced and the PR expression was negative. Serous adenocarcinomas failed to show an immunohistochemically expression for ER and PR.

The loss of alleles and mutations in p53 have been detected not only in endometrial carcinoma but also in atypical hyperplasia. These findings suggest that p53 inactivity is a late event in the endometrial carcinogenicity.

OUTCOME OF INTERNAL HEMIPELVECTOMY IN A PATIENT WITH MULTIPLE MYELOMA: CASE REPORT (Abstract). A patient treated for thyroid cancer was diagnosed with multiple myeloma in the context of trauma. After the pelvic tumor devascularization she underwent internal hemipelvectomy Type I + IIA Enneking Classification using polymerizing bioneutral gel embolization, "Glubran 2". The purpose of this case report is to demonstrate the importance of careful selection of treatment methods, together with adequate physical therapy in order to obtain favorable long-term results. **Keywords**: HEMIPELVECTOMY, MYELOMA, RECOVERY.

Internal hemipelvectomy is a surgical limb-sparing procedure used to treat malignant tumors of the pelvic ring. The most commonly used classification for hemipelvectomy is that by Enneking classification (1, 2), which distinguishes 4 types depending on the anatomical components removed, combinations of different types being also possible. We report the case of a female patient with multiple myeloma in association with multiple malignancies (3),who underwent Enneking Type I+IIA internal hemipelvectomy on January 21, 2008. The importance of adjuvant treatments and rehabilitation methods on patient outcome is discussed.

CASE REPORT

Patient E.G., 47-year-old female, was diagnosed on October 25, 2004 with nodular goiter and underwent surgical removal of the thyroid tumor. On April 13, 2007, the patient suffered an injury by falling from a height of about 1m with impact on the right hemipelvis. At physical and radiological examination a massive tumor involving the entire right iliac fossa was detected. The tumor was highly vascularized and its extra-compartmental component was displacing the iliac muscle together with the adjacent arteriovenous vascular groups.

On June 15, 2007 an angiography was performed. It detected a tumor occupying the right iliac fossa, highly vascularized, receiving blood supply from emerging vessels from right hypogastric artery and right lumbar artery IV. Tumor embolization was performed using Glubran 2, a bioneutral polymerizing gel,a total tumor devascularization being obtained (figs. 1, 2). On January 21, 2008, after a surgical biopsy was performed, the patient was diagnosed with myeloma. On the same day, the patient un-

derwent internal hemipelvectomy type I (iliac radical resection with gluteal muscles and sciatic nerve preservation) and IIA (excision of the whole acetabulum), according to Enneking classification (fig. 3).

The resection of the right hemipelvis was performed with the following margins 17x16x10 cm, together with the collection of a tumor mass measuring 11x10x9cm, which was consisting of translucent yellow-brown bulky tissue.

Macroscopically, the tumor occupied a part of the iliac fossa, expanding beyond the cortical component to the surrounding soft tissues and reaching the sacroiliac resection edge.

Microscopically, the osteomedullary tissue was infiltrated with a population of plasma cells. Rapid tests, together with immunohistochemistry studies confirmed the diagnosis of myeloma.

After surgery a rehabilitation program was initiated. After the removal of suture threads, 20 days after surgery, the patient was started on active and passive range-of-motion hip mobilization pool exercises. With the aid of two crutches, the patient resumed walking with left leg weight bearing and right leg in flexion up to 60 degrees, considering the possible risks of early right hip mobilization. A strengthening exercise program for gluteal and right thigh muscles was also started. Forty days after surgery, the patient began the progressive weight bearing on the affected limb. One year after surgery the patient started to walk without using any equipment. The patient presents a leg shortening of 8.7 cm together with a limitation of rotation movements. Up to now, the patient did not present any complication, did not require administration of analgesics, and has already exceeded the average survival rate, seven years after surgery.

DISCUSSION

Oliveira et al. (1) state that with adequate physical therapy patients who undergo internal hemipelvectomy without further reconstruction may walk again after the pelvic fibrous plaque forms in about 1-3 months after surgery. Our patient did so 40 days after surgery. She showed no recurrences or complications, a satisfactory functional outcome and a favorable long-term prognosis, which demonstrated a pattern of myeloma evolution after internal hemipelvectomy similar to that of other types of malignancies reported in the literature (1, 2, 4, 5). The patient does not require any pain medication unlike the patients who undergo amputation, is in good psychological state and socially integrated, results in agreement with previous studies (2, 4, 5).

CONCLUSIONS

In our patient, internal hemipelvectomy was the treatment option that spared the affected limb and avoided amputation, which is a traumatic radical alternative. Our particular case demonstrates a good functional recovery, regaining the ability to walk independently. The lack of complications and recurrences confirms the appropriate therapeutic selection. Indications for reconstruction should be reconsidered and individualized in order to achieve a long-term survival at the cost of weaker functionality.

ADDITIONAL DEMOGRAPHIC AND CLINICAL EVIDENCES ON THE RELEVANCE OF THE SYSTEMIC THERAPY IN ALCOHOL DEPENDENCE (Abstract). The modern treatment for alcohol dependence is still problematic, in many cases with the costs exceeding benefits. In these conditions a new management approach was developed lately, known as the systemic therapy. In this way, the crystallization and practical transposition of this new treatment approach is represented by the Clubs of Alcoholics in Treatment. These clubs are in fact a form of psycho-social intervention consisting of multi-family communities in order to maintain long-term abstinence from alcohol and to change their lifestyle and behavior. Thus, in the present paper we were interested in understanding the demographics of this systemic theory and how these aspects are influencing the final results of the therapy, as well as studying/confirming how relevant is this systemic approach on the management of alcohol dependence. Our results presented in this report bring additional evidences for the superiority of the systemic, multi-family approach of alcohol-related problems, as complemented to the standard medicinal therapy. Moreover, the data collected from patients in this study might suggest that patients with a higher educational level and therefore better capacity of understanding the information, with family support, and also with a better occupational insertion, have accepted to follow The Clubs of Alcoholics in Treatment program, with a subsequently better evolution. **Key words:** ALCOHOL DEPENDENCE, SYSTEMIC THERAPY, DEMOGRAPHICS.

Alcohol consumption is a universal widespread activity. In this way, some numbers regarding alcoholism provided by the National Institute of alcohol abuse and Alcoholism are showing that in 2013, 24.6 % of people ages 18 or older reported that they engaged in binge drinking in the past month, while 6.8 % reported that they engaged in heavy drinking in the past month (1). In addition, nearly 88,000 people (approximately 62,000 men and 26,000 women) die from alcohol-related causes annually, making it the third leading preventable cause of death in the United States (2,3).

However, the alcohol consumption patterns are variable. As a matter of fact, excessive consumption of alcohol can take many forms, from daily consumption of large quantities to repeated episodes of consumption with intoxication or from alcohol addic-

tion behavior to consumption resulting in impairments of health status. However, there is not a very clear distinction between social/occasional drinking of alcohol and abusive consumption. From the medical point of view, there are two notions that are associated with consumption in excess of alcohol: addiction and abuse (4).

There are various approaches in the literature regarding the management of the alcoholism (5,6). One of these approaches is regarding the problem of alcohol AS based on the ecological and social systemic theory, specifying that consumption of alcohol is actually a type of behavior, a way of life. The crystallization and practical transposition of this ideology is represented by the Clubs of Alcoholics in Treatment. These clubs are in fact a form of psycho-social intervention consisting of multi-family communities in order to maintain long-term abstinence from alcohol and to change their lifestyle and behavior (7). Moreover, alcoholism has a huge impact at the individual level, through medical, socio-familial and financial problems involved, but at the same time it is a major public health problem. Thus, alcoholism and the problems arising from it require a complex therapeutic approach, not only medical but also social and psychotherapeutic, centered both on the individual and his family.

Moreover, there are studies bringing evidence in support of a community-based management in post-hospital phase. For example, Mann and his collaborators have published a study that evaluated a model of community-based treatment combining a six-week period of hospitalization with one year of ambulatory therapy. The results of the research have shown that a subgroup of alcoholics appear to benefit from the community-based programs. This subgroup is characterized by a good social adjustment and their relatives' desire for active participation in the treatment (8).

In this way, in the present paper we were interested in understanding the demographics of this systemic theory and how these aspects are influencing the results of the therapy, as well as studying/confirming how relevant is this systemic approach on the managements of alcohol dependence.

MATERIAL AND METHODS

The present study involved clinical therapeutic evaluation of 85 patients with alcohol dependence within a period of 3 months. The patients evaluated in the study were in the evidence of the Clinical Psychiatric Hospital Socola in Iaşi. The patients have been diagnosed with alcohol dependency in accordance with the criteria DSM-IV tr. These patients presented or not psychiatric or somatic comorbidity (with the exception of those specified in the exclusion criteria). All patients received standard medication for alcoholism (mood stabilizers, benzodiazepines and vitamin therapy).

Patients included in the study were patients aged between 18 and 63 years, with alcohol dependency (according to DSM-IV tr), who have expressed their desire for the cessation of alcohol. The following exclusion criteria have been used: patients who have completed treatment or psychotherapy for alcohol dependence during the past 90 days, patients without discernment, other associated somatic decompensated conditions or which could worsen the patient clinical status during the participation in the study.

After screening, patients were distribut-

ed into two approximately equal groups (based on their consent to participate in the therapy carried out in the Clubs of Alcoholics in Treatment). Thus, 42 patients with alcohol dependence have received standard medical treatment and entered the program of Hudolin systemic psycho-social intervention and 43 patients with alcohol dependence have received only standard medical treatment.

The evaluation of patients with alcohol dependence was performed with the AUDIT scale (The Alcohol Use Disorders Identification Test) and the quality of life scales (QOL 16 The Quality of Life Scale).

The AUDIT scale (Alcohol Use Disorders Identification Test) is a questionnaire which can be self managed, containing 10 items and assessing the behavior and problems associated with alcoholism, as well as harmful consumption of alcohol (items 1 to 3), the behavior associated to consumption (items 4-6), adverse reactions to alcohol (items 7-8) and the problems associated with alcohol (items 9-10). Items 1-8 scores vary from 0 to 4, while items 9-10 may be scored 0, 2 or 4. The scores range between 0 and 40, higher scores being associated with a greater risk. Scores between 8 and 12 indicate a harmful consumption, while the scores 13-40 indicate alcohol dependency. Studies performed on this scale show a high sensitivity and specificity (9). The level of alcohol dependence and consumption prior to inclusion in the study was assessed through this scale at the time of the inclusion in the study.

The quality of life scale QOL 16 (The Quality of Life Scale) originally developed by Flanagan in the 1970s (10), is a scale used to evaluate the quality of life in people suffering from chronic conditions. Is a Likert Scale whose items have 7 response possibilities ranging from: delighted (=7) satisfied (=6), rather satisfied (=5), mix (=4), rather dissatisfied (=3), miserable (=2), awful (=1). It is composed of 16 items, with an additional item compared to the original version, namely the 16th item, which refers to the independence degree and self-care ability. The other five evaluated fields include: physical and material well-being, relations with others, social, civic and community activities, and personal development and fulfillment, recreational activities. It is a self-managed scale whose total scores range between 16 and 112. Higher scores indicate an increased level of quality of life.

DATA ANALYSIS

The sampling included as stages the determination of the sampling frame (screening of Socola Hospital patients) and the statistical analysis with appropriate use of statistical tests. There were used descriptive methods (for demographic data analysis), comparative methods (single Factor Anova test), as well as prospective methods for tracking the evolution in time of the patients. The data were loaded and processed using the statistical functions in Microsoft Excel (Microsoft Corp.) and SPSS16 statistical analysis package (SPSS Inc.). The results are expressed as mean ± standard deviation (SD). Statistical interpretation took as reference point the value of 0.05, p (Sig.) <0.05 with statistical significance.

RESULTS

In this way, several preliminary results of the current study will be presented, with particular reference to the demographics obtained, as well as changes in quality of life (up to 3 months).

Analysis of demographic data

In terms of gender, all patients included in the study were male. Regarding the age of the patients included in the group who benefited from the combined therapy (systemic plus pharmacological), the average age was 48.6 ± 10.2, with the standard error of 1.53, while the patients who received standard therapy only, had a relatively close average age, 42.7 ± 10.5, with an standard error of 1.55.

Also the statistical analysis for the background of origin shows a slightly higher percentage of people coming from rural areas (52.17%), when compared to patients who come from urban areas (47.82%) within the group treated with standard medication, while if referring to the patients who opted for systemic therapy, a higher percentage of people with urban background (63.63%) was registered, as compared to rural areas (36.36%).

In terms of marital status, in the patients included in the associated therapy, the percentage of married patients is the highest (70.45%), followed by divorced patients (13.63%), unmarried (9%) and widowers (6.81%). In patients who were included in the standard therapy, most patients were unmarried (44%), followed by married (28%), divorced (24%) and widower patients (4%).

Also, most patients from both groups have an average education level and none of them is unstudied. Thus, for patients who have opted for the combined therapy, a percentage of 38.63% have not graduated from high school, 27.27% of them have graduated from 12 classes, a percentage of 20.45% have post-secondary and faculty studies and only 2.2% have only 8 classes or less. Also, in the case of the second group, most patients have not graduated from high school (44%), followed by patients with 8 classes or less (41%), 11% have graduated from high school and only 4% of them have post-secondary studies.

In both groups of patients, most of them were without occupation (47.72% in the group with combined therapy and 69% in the lot with standard therapy). Close percentages between the two batches were recorded for the retired patients (22.72 % in the group with combined therapy vs. 24% in the group with standard therapy).

Only the percentage of employee patients clearly differ for the two groups, a much higher percentage of employees being recorded in the group subjected to combined therapy (29.54%), as compared to the group that received the standard treatment (7%).

In both groups most patients were smokers, and the proportion between smoker and non-smoker is preserved in the two batches, as 61.36% patients were smokers in the combined therapy group, when compared to 69.56% in the standard therapy group.

The AUDIT scale was applied to all patients at the inclusion in the study. However, there were no significant differences in terms of statistics between the 2 groups of treatment, which is important as it proves the homogenity of the two batches ($F(1,89) = 3.94$, $p = 0.11$) (fig. 1).

Also, **the scale for the quality of life** QOL 16 was applied to each visit. On the baseline, the means for the scale between the two groups of patients were very close, with the mean for the combined therapy group being 74.8 ± 18.64, while for the standard therapy group it was 73.6 ± 9.6. As seen in fig. 2, there were no significant differences between the quality of life scale scores of the two groups of patients

(F=0.11, p=0.7).

Still, the application of the QOL16 scale at one month, highlighted significant differences between the two groups, with a higher mean for the combined therapy patients (88.1 ± 15.4), when compared to 80.25±14.4, the mean of the other group of study (F=4.29, p=0.04) (fig. 3).

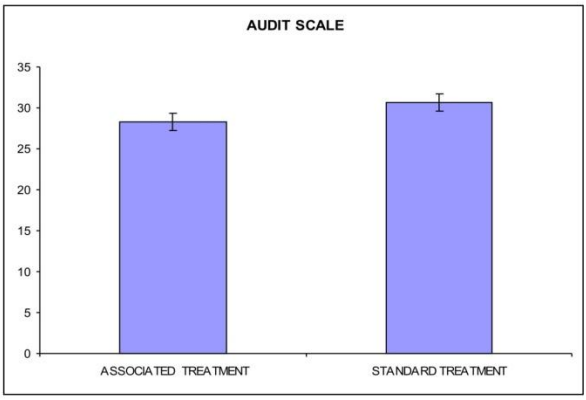

Fig. 1. Comparison among AUDIT scale scores for the two gropus of patients.

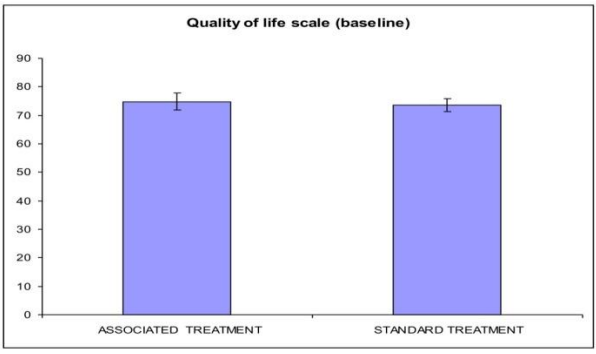

Fig. 2. Comparison between QOL16 scores at baseline for the two groups of patients.

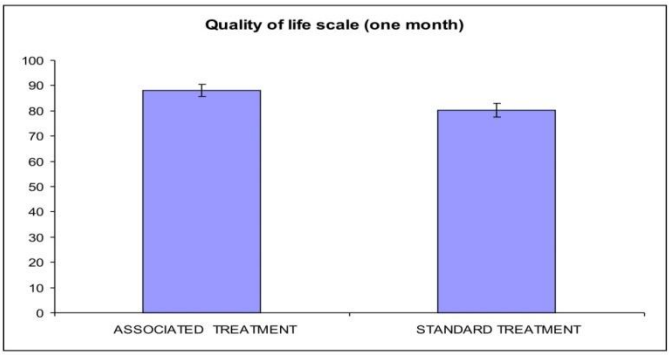

Fig. 3. Comparison between QOL 16 scale scores – one month between the two gropus of patients.

Consequently, the QOL 16 scale was applied at periods of 3 months and increased statistical significant differences between the 2 groups of patients were also obtained (F=10.71, p= 0.01). Moreover, as it can be seen in the chart below, the difference between average values was approximately 10 points (fig. 4).

Fig. 4. Comparison between QOL16-3 months between the two groups of patients.

DISCUSSION

In this way, the data presented in this article is providing additional evidences for the superiority of the systemic, multi-family approach of alcohol-related problems, as complemented to the standard medicinal therapy.

Also, regarding the demographical results we obtained in the current report, our study was applied only on male population, as a result of the division profile where the sampling was made. There is also a predominance of the urban environment in the case of the group that benefited from systemic therapy, and this could be explained by the particularities for the location of the Clubs of Alcoholics in Treatment, as they are organized mainly in the city, while the patients from rural areas have somehow a reduced access possibility.

Also, in terms of marital status, the majority of patients who have opted for combined therapy were married (70.45%), while the majority of patients who followed standard therapy were unmarried (44%). In fact, one of the features of the systemic approach to alcoholism is the active participation of the family in the recovery process of the addicted persons. The same issue could be interpreted also by the fact that marital status can confer an additional motivation (either through the encouragement and support of the family, either by responsibility and commitment assumed by the patient in front of his family) in committing to this type of therapy. At the same time, it may be that the spouse is more available and more interested in participating at these meetings than a partner without marital commitment.

With regard to the level of education, a relative symmetry for the considered groups has been noticed. No patient in the study was unschooled. The group of less schooled patients is the one that received just the standard therapy, while most patients with intermediate and higher level of education were in the category of patients which benefited from the combined therapy. We can speculate, as a result of these aspects, that the level of education could be a positive factor in the patient's desire to

become abstinent, as well as in the capacity of understanding the potential benefits brought by a systemic approach, thus giving the dependent patient an extra motivation towards the acceptance of new solutions to the problem of alcoholism.

From the point of view of their occupation, the majority of patients in both groups were without occupation. This aspect could be interpreted differently. Either alcohol dependence has led or contributed to the loss of the service, or adherence to a service is a protective factor for alcoholism. Considering that most patients who were employed were in the combined therapy group, the explanation that the service could further motivate the individual wishing to treat himself by maintaining a certain social status and financial support, as well as fear of dismissal, may be justified.

Further analysis of tobacco consumption, has revealed that the majority of patients in both treatment groups were smokers. Incidentally, this was to be expected considering that there is a well-known correlation between alcohol consumption and tobacco. In this way, it is estimated that 80% of alcohol addicted persons smoke. In our study, we found smaller percentages of smokers (a general percentage of 65%) than in the general population, with a slightly higher percentage (almost 70%) in the standard treatment group. The results of studies that examined the connection between smoking and alcohol showed that nicotine not only correlates with alcohol consumption, but may also be a prediction factor for the severity of alcoholism (11, 12).

Additionally, our statistical data showed very clearly the homogenity of the studied groups, which constitutes a necessary prerequisite for comparing the results obtained in the course of research (13). In this way, no significant differences between groups were found in terms of demographic data.

The severity of alcohol dependence was assessed using the AUDIT scale. This was done for all the patients from the study, even from the beginning (before patients were divided into two groups of treatment). The AUDIT scale assesses the behavior and problems associated with alcoholism and harmful alcohol consumption. The application of this scale revealed high overall scores, indicating an increased severity of the addiction.

Also, very importantly, calculating the total scores means after the distribution of patients in different groups revealed similar mean values (around 30 for both groups), without significant statistical differences. This indicates the correct prerequisites for our research performed here, having homogeneous groups of study and a high level of alcoholism severity for the both groups of patients. In fact, this is supported by the scientific data showing that increased scale scores predict the severity of alcoholism (14, 15).

Thus, the data collected from patients in this study might suggest that patients with a higher educational level and therefore better capacity of understanding the information, with family support, and also with better occupational insertion, have accepted to follow The Clubs of Alcoholics in Treatment program with a subsequently better evolution. Also, it seems that the systemic therapy associated with standard therapy provides additional value in terms of improving the quality of life.

CONCLUSIONS

The data presented in this study shows the additional benefits that systemic therapy provides for patients with alcohol related problems and their families. In this way,

our results can be resumed into the following conclusions:

1. The systemic method additionally improves the quality of life in patients with alcohol dependence, when it is associated with standard therapy.

2. The improvement in the quality of life is initiated on the very beginning of therapy, starting with the first month of systemic therapy associated with standard treatment.

3. The systemic method brings also long-lasting benefits, as demonstrated by the increase in time for the quality of life scale scores.

4. Patients with a higher educational level, with family support, and also with better occupational insertion have a better evolution.

5. The systemic method has exhibited a beneficial role in the post-hospital therapeutic phase management for patients with alcohol dependence, when it is associated with standard therapy.

ZINC IMBALANCE AND THE OPPORTUNITY OF ZINC SUPPLEMENTATION IN ALCOHOLICS AND DRUG USERS (Abstract): Zinc deficiency is well-documented to be associated with alcoholism, being considered a consequence of unbalanced eating habits in such patients. The present review focuses on zinc imbalance in drug addicts and on the possible beneficial role of zinc administration as dietary supplement. All relevant literature published up to May 2015 was searched. The search was performed using the keywords "zinc" plus "alcoholism", "addiction", "dependence", and the name of different drugs of abuse (classes or representatives). Human and animal studies were included. In alcoholism, zinc deficiency is not only due to malnutrition and malabsorption which are characteristic to this condition, as there is evidence of increased elimination and altered distribution of zinc. In opioid addicts, zinc deficiency is also commonly encountered and opioid administration in animals determines changes in zinc distribution. Studies regarding the zinc status in other drug abusers are inconsistent. Zinc deficiency in drug addicts also seems to affect some neural mechanisms involved in the downward spiral of addiction, as decreased zinc is associated with depression-like symptoms, known to induce drug-taking behavior. Moreover, zinc deficient animals are resistant to dynorphin-induced feeding. **Conclusion**: Based on evidence in the medical literature, the present review pleads for a beneficial role of zinc supplementation in alcoholics and opioid-users, not only in order to correct or prevent a metabolic imbalance, but also to influence some cerebral mechanisms involved in drug-taking behavioral patterns.
Keywords: ZINC, DEPENDENCE, ADDICTION, ALCOHOLISM.

Zinc, the second most important trace element in humans (after iron) (1), plays mainly structural and catalytic roles (2). It is important for the antioxidant defence, as a co-factor of Cu-Zn superoxide dismutase (3). Zinc finger proteins acting as transcription factors regulate gene expression (4). The brain is one of the organs with highest Zn^{2+} levels, containing approximately 1.5% of the estimated 2-3 g of zinc in the human body. Within brain zinc is nonuniformly distributed: the olfactory bulb has the highest level, followed by the frontal and parietal cortices (5). Within the central nervous system, zinc influences synaptic plasticity, hormone release, and nerve impulse transmission (6).

Zinc deficiency affects over 15% of world population and the prevalence of inadequate intake varies from 7.5% in high-income regions to 30% in South Asia (7). More than 80% of pregnant women

have a zinc intake lower than recommended (8). Severe deficiency is rare, but mild and moderate zinc deficiency is widespread. Deficiency symptoms are rather nonspecific, including growth retardation, male hypogonadism, delayed wound healing and cell-mediated immune dysfunction (9), but response to repletion occurs very fast (10). Disorders mainly related with brain dysfunction (behavioral changes, depression, emotional instability, anxiety, socializing deficits, impaired memory and learning, anorexia, autism spectrum disorders, attention deficit hyperactivity etc.) are frequently associated with zinc deficiency (11, 12). In some of these conditions, it is debatable if decreased zinc is a consequence or a cause. Under moderate zinc deficient diet, brain zinc is maintained within normal limits, due to increased uptake (13).

Addiction is a chronic, relapsing disorder, characterized by loss of control over drug-taking. The association between zinc deficiency and alcoholism is well-known, being considered a consequence of unbalanced eating habits in such patients. There is also evidence of decreased zinc levels in opioid-users. On the other hand, zinc deficiency reduces food intake and causes depressive-like symptoms, known to induce drug-taking behavior. In this context, the present review focuses on zinc imbalance in drug-addicts and alcoholics and aims at discussing the possible beneficial role of zinc administration as dietary supplement in such persons.

All relevant literature up to May 2015 was searched. The search was performed using the keywords “zinc” plus “alcoholism”, “addiction”, “dependence”, “smoking” and the name of different drugs of abuse (classes or representatives). Human studies on the status of zinc and other metallic trace elements possibly interacting with zinc in addicts (alcoholics including) were included. Animal studies on the interaction between addictive substances and zinc metabolism were also considered.

In order to discuss the opportunity of zinc supplementation, searching strategies were consequently adapted.

RELEVANT FINDINGS

There are many studies reporting low zinc levels in drug addicts and drug users, most of them referring to alcoholics and opiate users. To our knowledge, studies on zinc levels in nicotine addiction or cigarette smoking are scarce, whereas those referring to zinc status in users of psycho stimulants or cannabis are absent. Low zinc status in case of different types of drug addiction is documented to represent rather a consequence of the toxic capacity to influence zinc distribution and elimination than a factor predisposing to drug-seeking behavior; however, malnutrition is common among drug addicts (14), especially in women (15), and this might represent an explanation for the low zinc levels in these subjects.

A. ***Alcohol***

a. *Human studies*. Decreased serum zinc in alcoholics has been widely reported and known for a long-time. About 90% of alcoholics, with or without liver disease, were reported to have inadequate dietary zinc intake (16). It is believed that long-term ethanol consumption is responsible for zinc malabsorption, since it was shown that decreased zinc absorption only occurs in patients with alcohol-induced cirrhosis, where $ZnCl_2$ labeled with 65Zn was absorbed in a reduced proportion compared to controls (37±17% vs. 55±16%, $p<0.01$),

whereas in non-alcoholic cirrhotic patients zinc absorption was similar to that of healthy controls (47±11%) (17). Similar results on reduced zinc absorption were also reported by Dinsmore et al. (18). In delirium tremens patients, zinc is decreased in both serum and erythrocytes (19). Alcohol users' exhibit increased urinary zinc elimination (20); the reduced zinc-binding capacity of albumin in patients with decompensated alcoholic cirrhosis is probably responsible for this (21). Controversial data regarding zinc metabolism in alcoholic cirrhosis have also been published: Mills et al. (22), reported increased intestinal absorption, whole-body content and total daily elimination of zinc in alcoholic cirrhosis, but with no changes in the biological half-life of zinc.

b. *Animal studies*. Interestingly, one study investigating the effect of 20% ethanol solution administration (intragastric, 2 g/kg daily) for five days, revealed that, on the day 5 animals presented higher zinc levels in serum and heart, but decreased zinc concentration in brain, lungs, kidney, liver, spleen and muscles (23).

B. ***Opioids***

a. *Human studies*. Low serum zinc levels are reported in heroin users, with a slight tendency to increase during detoxification, yet not reaching control level (0.815±0.144 mg/L on admission for treatment and 0.859±0.205 mg/L at the end of hospitalization in opiate users vs. 1.118±0.114 mg/L in controls) (24). Moreover, zinc deficiency is correlated with the period of abuse in heroin addicts (25). Low serum zinc level is accompanied by increased serum copper level (26), the same being reported for the intraerythrocytic levels of zinc and copper. The antagonism between copper and zinc in both intestinal absorption levels and biological actions is well documented (27); the competition between zinc and copper at the level of DMTa transporter seems to be responsible for this. Copper facilitates zinc elimination though urine, but copper excess facilitates zinc storage (28). The antagonism between zinc and cupric bivalent ions occurs in the conditions of certain chemical similarities between them. So, as decreased zinc is accompanied by increased copper, it is reasonable to consider that zinc deficiency has better conditions to more clearly manifest in opioid users. Zinc level in the cerebrospinal fluid of former heroin addicts is lower than in controls, but generally within normal ranges (29). During methadone detoxification in opioid addicts, zinc elimination is strongly increased (600±50μg/g creatinine in patients vs. 300±50μg/g creatinine in controls, $p<0.001$), while copper elimination is slightly, but significantly decreased (23±3μg/g creatinine in patients, $p<0.05$ vs. controls) (30). On the other hand, heroin samples on the illegal market were shown to contain variable amounts of trace elements, including zinc, but these have little contribution to zinc intake and product toxicity (31) and they are believed to appear from the metallic container used in the processing/cutting stage (32).

b. *Animal studies*. Morphine administration in rats decreases the serum zinc level, but it increases liver cytosolic zinc and metallothionein (a family of cysteine-rich proteins involved in both zinc and copper metabolism) levels. If the effect of morphine on liver metallothionein levels is mediated mainly by the morphine effect on specific receptors (being antagonized by naloxone), zinc accumulation in the does not recognize this type of mediation, as

naloxone does not alter it; however, glucocorticosteroid and β-adrenergic mediation seem to be at least in part responsible for the increase in zinc and metallothionein liver levels, as their antagonists (RU 486 and labetalol, respectively) diminish that increase (33). Increased liver metallothionein levels (3-folds vs. control) were also reported by other authors (34), these being accompanied by increased brain and kidneys metallothionein levels (5 and 2-fold, respectively vs. controls). Interestingly, one study on the effect of morphine escalating doses in mice (intraperitoneal; 15 mg/kg on day 1; 30 mg/kg on day 2; 45 mg/kg on day 3; 60 mg/kg day 4; 50 mg/kg on day 5) showed on day 5 animals presented increased serum zinc concentration and increased zinc levels in the heart, spleen and muscle, but decreased in the brain, lungs, kidney, and liver (23). Intracerebroventricular administration of the δ-opioid agonist (D-Pen2, D-Pen5) enkephalin results in decreased Zn^{2+} content in parietal cortex, hippocampus and striatum; the effect is time- and dose-dependent and it is antagonized by naloxone pre-treatment (5).

C. ***Nicotine addiction and smoking***

a. *Human studies*. A positive association between smoking and serum zinc concentration ($p=0.0003$) was evidenced, but only in women (35), whereas other studies report no influence of smoking habit on zinc levels in urine (36), placenta, cord blood and maternal blood of women at delivery (37). However, the hair of tobacco smokers contains less zinc, calcium, magnesium, iron, and copper compared to controls (38).

b. *Animal studies*. Infusion of 50 mg nicotine for 21 days in rats did not modify serum zinc levels, but increased Cu-Zn superoxide dismutase activity (39).

DISCUSSION

In alcohol addiction the associated malnutrition and malabsorption are considered the cause of lower magnesium and zinc levels. However, increased urinary zinc elimination, probably related to decreased albumin capacity to bind zinc and zinc altered distribution, is also involved. Eating-related characteristics, as well as kinetic particularities, may also explain the tendency to zinc deficiency in opioid addicts. On the other hand, when discussing the eating habits, it should not be disregarded that zinc deficiency is associated with anorexia and zinc ions are important regulators of eating and liquid-intake patterns. For instance, acute third ventricle injection of minute zinc amounts (3 to 300 pmol) induces a dose-dependent antidipsogenic action in dehydrated rats, almost complete at the highest dose. The effect is reversed by naloxone, indicating that it may be, at least in part, due to stimulation of central opioid peptides (40). Zinc-deficient animals have low levels of hypothalamic dynorphin (a leucine-enkephalin opiate peptide and a potent inducer of spontaneous feeding) compared to *ad libidum*-fed controls and are also relatively resistant to dynorphin-induced feeding (41). Zinc ions inhibit anorexigenic proopiomelanocortin neurons in the hypothalamic arcuate nucleus (42). All these suggests that in zinc deficiency-induced anorexia appetite dysregulation is mediated via the endogenous opioid system, including alterations in receptor affinity, a post-receptor defect and alterations in the dynorphin synthesis and/or release.

Decreased zinc influences certain mechanisms responsible for the downward

spiral of addiction, as it is associated with depression-like symptoms (11, 12), which are known to induce drug-taking behaviour (43). Normalizing zinc level in zinc-deficient opioid-users and alcoholics may reduce the use of drug by attenuating depressive symptoms.

As to opioid dependence, there are studies revealing increased naloxone-precipitated withdrawal by zinc chelators (in mice) (44) and decreased withdrawal due to zinc administration during the induction phase of morphine-dependence (in rats) (45). This is an argument for a possible beneficial role of zinc supplementation in opioid users or addicts and it can be explained by zinc ions capacity to decrease opioid binding to μ-opioid receptors, as there is evidence that Zn^{2+} lowers the affinity of different ligands to receptors (46). The idea is reinforced by the low levels of zinc in opioid users.

Assessment of trace element status is often disregarded in drug users. Zinc deficiency is considered a consequence of reduced intake or impaired absorption in alcoholics, but it seems to be also related to increased elimination. In drugs addicts zinc deficiency is not just a dietary imbalance with metabolic consequences, but it also may contribute to the persistence of drug-taking behavior by inducing depressive symptoms. Also, zinc deficiency favors anorexia, which may contribute to further imbalances.

CONCLUSIONS

Our present review pleads for a beneficial role of zinc supplementation in opioid users and alcoholics. This is based not only on the low zinc levels documented in ethanol and opioid users, but also on the fact that correcting zinc status may improve the eating habits and lower the craving by attenuating depressive-like symptoms. The low toxicity of orally-administered zinc salts is an additional argument. The status of trace elements in drug users should be more carefully assessed.

THE EFFECT OF COBALT CHLORIDE PRECONDITIONNING ON PACLITAXEL-INDUCED PERIPHERAL NEUROPATHY (Abstract) **Introduction**: Recent studies indicate that Cobalt Chloride (CoCl2) modulates mitochondrial activity. There is emerging data suggesting that Paclitaxel-induced peripheral neuropathy (PIPN) is a consequence of the drug's mitochondrial toxicity. AIM: to assess the effect of CoCl2 preconditioning on PIPN in an animal model. **Material and method**: PIPN was induced by 7 daily consecutive i.p. Paclitaxel (PXT) administrations. Male BALB/c mice were divided into three groups as follows: group A - CoCl2 (12.5 mg/kg b.w.) for three weeks (preconditioning) followed by 1 week of PXT, group B - saline for three weeks, followed by 1 week of PXT and group C - saline for four weeks. Thermal and mechanical allodynia were assessed by means of paw withdrawal latency (PWL). **Results**: In group A, CoCl2 preconditioning lead to a decrease in both thermal and mechanical PWLs. 7 days after the last dose of PXT, however, values returned to normal in group A and allodynia for both thermal and mechanical stimuli was noted in group B ($p<0.05$). **Conclusions**: CoCl2 preconditioning seems to protect against PIPN. Although CoCl2 administration decreased thermal and mechanical PWLs, subsequent P administration did not lead to the persistent mechanical and thermal allodynia that was noted in the P-alone group. Further studies are required for determining the exact relationship between CoCl2 and PIPN. **Keywords**: PACLITAXEL, PAINFUL NEUROPATHY, COBALT CHLORIDE

Painful peripheral neuropathy (PPN) is one of the most frequent side effects of Paclitaxel (PXT) – a chemotherapy drug used in the treatment of breast, lung, ovarian and germinal cancers. Its mechanism involves blocking the cell cycle, through centrosomal impairment, induction of abnormal spindles and suppression of spindle microtubule dynamics (1). This antitumor mechanism does not explain, however, the pathogenesis of PXT-induced peripheral neuropathy (PIPN). Recent research suggest that there is a connection between PIPN and its mitochondrial toxicity (2,3).

Cobalt chloride (CoCl2) is a chemical compound widely used in research due to its ability to induce chronic HIF-1 (hypoxia inducible factor-1) activation and, thus, to mimic cellular hypoxia by activating the genes responsible for adapting to low oxygen concentrations. Moreover, CoCl2 stabilizes this factor, which is usually inactivat-

ed once normal oxygen concentrations are again detected. Studies suggest that hypoxic preconditioning has cardio- (4), reno- (5) and neuroprotective (6) effects.

A 2012 study (7) indicates that CoCl2 preconditioning (due to hypoxia adaptation) leads to increased physical performance and enhances mitochondrial metabolism in mice. Other studies, such as the one of Jones et al. (8) demonstrate the protective effect of CoCl2 against perinatal hypoxic-ischemic lesions.

In a recent study, we showed that daily CoCl2 administration for 3 weeks has anti-inflammatory effects in a murine pain model and leads to a decrease in pain behavior, especially during the second phase of the formalin test (9).

The present study aims to investigate the effects of CoCl2 preconditioning on Paclitaxel-induced peripheral neuropathy.

MATERIAL AND METHODS

Animals: 24 male BALB/c mice, weighing 27 to 30 grams were used. Throughout the experiment, the animals had ad libitum access to water and food; the mice were habituated with the testing environment 2 hours prior to testing. The study design and experimental procedures described in this article are in accordance with the European Council Directive 2010/63/EU and follow the guidelines for investigations of experimental pain in conscious animals issued by the University of Medicine and Pharmacy "Gr. T. Popa".

Drugs used in the experiment: CoCl2 (Sigma-Aldrich Chemie BmbH, Germany) and Paclitaxel (Sindan Pharma, Romania); the substances were administered intraperitoneally; doses are in mg per kg body weight (mg/ kg b.w.).

Thermal and mechanical allodynia were assessed by:

Hargreaves, or plantar, test (Hg) was used in order to assess thermal allodynia. Mice were placed in transparent Plexiglas cases. Underneath the heat-conducting floor, a mobile radiant heat source (Plantar Test-37370 UgoBasile) was placed directly under the animal's paw; we measured the time between applying the heat stimulus and the moment when the animal withdraws its paw – response latency to thermal stimuli (paw withdrawal latency – PWL) (10).

The von Frey test, performed by means of the automatic von Frey method, (vF), was used to assess mechanical allodynia. Mice were placed in transparent cases with a wire-mesh floor. Underneath, a mechanical device with a thin filament (Dynamic Plantar Aesthesiometer 37450, UgoBasile) was used to apply increasing pressure onto the plantar side of the animal's paw. We measured the time between applying pressure and the moment when the animal withdraws its paw – response latency to mechanical stimuli (paw withdraw latency – PWL) (11).

The average of three different measurements for each paw (right and left) was used for statistical evaluation, both for thermal and for mechanical allodynia. Hyperalgesia was quantified as the percentage decrease in withdrawal latency (DWL) when compared to baseline:

% DWL = (baseline value - measured value) x 100 / (baseline value).

Study design: PIPN was induced by intraperitoneal administration of 2 mg/kg b.w. PXT for 7 consecutive days. The mice were divided into 3 groups (n = 8 mice/group) as follows: group A – CoCl2 (12.5 mg/kg b.w.) daily, for 3 weeks (preconditioning), then PXT for a week; group

B – 3 weeks of daily saline administration, then PXT for a week; group C – 4 weeks of daily saline administration. The CoCl2 dose was selected in accordance with published data (9). Thermal and mechanical allodynia were evaluated at the beginning of the experiment (baseline), then weekly during CoCl2/saline treatment and twice a week after PXT administration and until the end of the experiment. All tests were performed before the daily administration of CoCl2/PXT/saline. The animals were monitored for 7 weeks.

Statistical analysis: The results are expressed as DWL or as average±standard error. Statistical evaluation was performed by means of the SPSS v.20 software – ANOVA analysis with post-hoc Tukey test. Significance level was set at .05.

RESULTS

Effects on mechanical allodynia

Chronic CoCl2 administrations lead to a progressive decrease of the response latency for mechanical stimuli (vF test). Thus, after two weeks of treatment, PWL average for group A was 6.91±0.12s, while in groups B and C, the average values were 7.84±0.15s and 7.96±0.41s, respectively ($p<0.02$); after three weeks, the average PWL for group A was 5.77±0.26s, while for groups B and C, PWL averages were 7.94±0.08s and 7.31±0.47s, respectively ($p<0.01$). At that time, the CoCl2 treatment group had a response latency 24.8% lower compared to the beginning of the experiment (fig. 1). ANOVA analysis indicated a significant substance effect for days 14 and 21 of the experiment with $F(2, 5.3)=4.73$, $p=0.02$ at day 14 and $F(2, 19.9)=12.56$, $p<=0.0001$ at day 21.

After the last PXT dose (for groups A and B), in the 28th day of the experiment, the response latency of CoCl2 preconditioned mice increased close to baseline values. Thus, in the last day of chemotherapy (CHT), the average was 7.63±0.51s for group A, 7.33±0.43s for group B and 7.41±0.4s for group C ($p>0.05$). Two weeks after CHT, in the Paclitaxel-alone group (group B), a significant decrease of response latency for mechanical stimuli was noted, with average values of 5.69±0.53s, 27.5% lower than baseline values ($p=0.02$); at that time, the average value for group A was 8.01±0.69s and the average value for group C (control group) was 7.52±0.42s. Subsequently, sensitivity to mechanical stimuli increased only for PXT treated mice, with a maximum 41% decrease in response latency compared to baseline ($p=0.002$); for the CoCl2 preconditioned group, maximum decrease in averages after PXT treatment was 2.9% when compared with baseline (7.44±0.5s). At the end of the experiment, the average values of group B remained 13% lower than baseline, while in the other two groups, average values varied by 1-3% when compared with baseline (fig. 1.).

There were no statistically significant differences between baseline values in the three groups.

Effects on thermal allodynia

Chronic CoCl2 administration determined a transient decrease of response latency to thermal stimuli (Hg test). After the first week of CoCl2 treatment, PWL average in group A was 6.34±0.23s, while in groups B and C is was 8.06±0.43s and 7.92±0.23s respectively ($p=0.03$); ANOVA analysis indicated a significant substance effect for day 7, with ($F(2, 14.6)=9.08$, $p=0.001$). Subsequently, response latency values of CoCl2 treated mice increased and, after the third week, reached a higher

than baseline average (fig. 2.).

After the last PXT dose (for groups A and B), in the 28th day of the experiment, the response latency of CoCl2-treated mice remained constant, while for the mice treated with PXT alone, a decrease of 18.65% was noted. Starting with the 6th day after CHT, the difference between group B and the other two groups became statistically significant. Mice treated only with PXT had lower response latencies, with up to 45% decrease when compared to baseline ($p<0.05$ for all measurements) (fig. 2.). At that time point, in group A, average values were similar to baseline. In the last day of the experiment, the average value in group B was 3.92±0.43s, while in groups A and C, it was 10.81±0.92s and 9.01±0.81s, respectively.

There were no statistically significant differences between baseline values in the three groups.

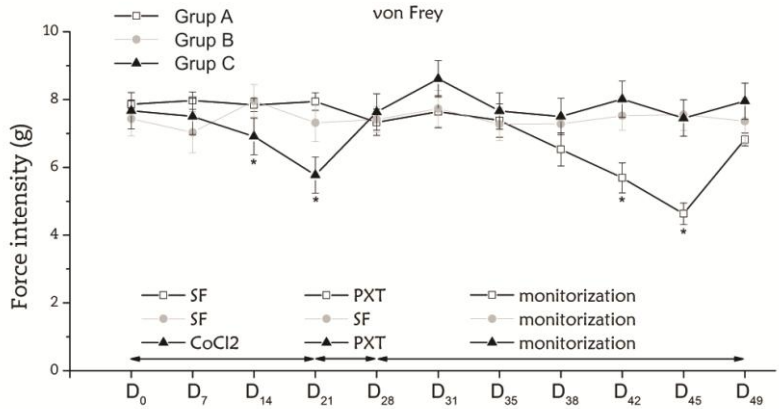

Fig. 1. The effect of CoCl2 on response latency after mechanical stimuli. For each group, treatment and motorization time-frames are mentioned. * - $p<0.05$ - Tukey post-hoc

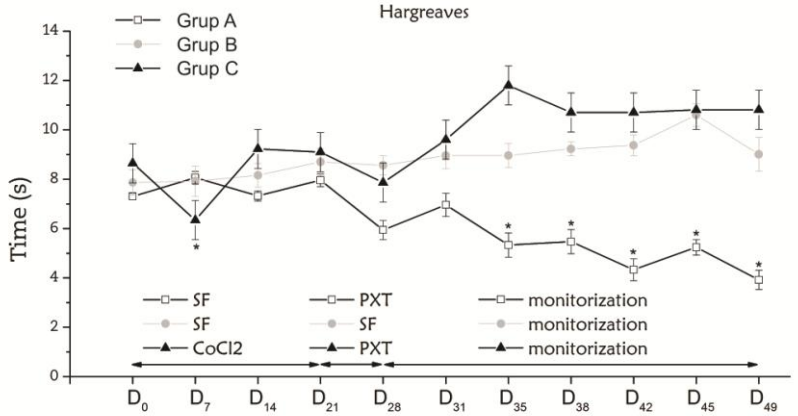

Fig. 2. The effect of CoCl2 on response latency after thermal stimuli. For each group, treatment and motorization time-frames are mentioned. * - $p<0.05$ - Tukey post-hoc

DISCUSSION

CoCl2 induced thermal and mechanical allodynia after one week of administration; thermal allodynia was transient, while mechanical allodynia persisted until the end of CoCl2 treatment (3rd week of the experiment). These results are in accordance with published data (9) and indicate a neurotoxic effect of CoCl2, possibly due to the substance's affinity for the nervous tissue (12). However, after PXT administration, response latency after both thermal and mechanical stimuli returned to baseline values in CoCl2 group and significantly decreased in the PXT-alone group. In group B, a significant and persistent thermal and mechanical allodynia appeared after CHT, with response latencies 41% lower than at baseline. The protective effect of CoCl2 preconditioning can be explained by CoCl2's stimulating effects on mitochondria.

Several studies suggest that PXT induced neuropathy is a result of its mitochondrial toxicity. For example, a paper published in 2014 indicated that, by blocking the sigma-1 receptors (which are involved in mitochondrial calcium homeostasis) in a mouse PXT neuropathy model, PIPN is can be prevented (13). Another study revealed the presence of mitochondrial anomalies in A and C fibers by microscopy analysis of the saphenous nerve; this led the authors to suggest that mitochondrial modifications are the main mechanism responsible of PIPN (3). Janes et al. suggested that the presence of PIPN is strongly related to mitochondrial superoxide dismutase inactivation and to decreased ATP production in the axons of the primary sensitive neurons (14).

There are several in vitro studies highlighting the effect of PXT on mitochondria. For instance, Xiang et al. performed in-vitro administration of PXT to isolated mitochondria and measured the organelle's membrane potential ($\Delta\psi m$) by means of flow citometry. The results showed a dose-dependent decrease in potential value; these changes were not observed when the experiment was carried out with Cisplatin or actinomicine D (15).

Another in-vitro study revealed the direct influence of PXT on mitochondria isolated from human cancer cells (neuroblastoma), in which PXT administration lead to the release of cytochrome C. Thus, the authors suggested that even the apoptotic effect of PXT may result from its direct interaction with the mitochondria (16).

Even though the exact mitochondrial component responsible for PIPN is unknown, all the above-mentioned studies point toward a common mechanism: mitochondrial toxicity in the axons of the primary sensitive nerves following a loss of mitochondrial bioenergetics (14). Furthermore, a recent study (17) assessed the effect of two mitochondrial modulators - ascorbic acid and curcumin – on pain; results showed that these substances decreased pain behavior in the second phase of the formalin-induced pain test, considered to be an equivalent of neuropathic pain (18).

Our results can also be explained by the beneficial effects of hypoxic preconditioning in itself. In humans, training in a hypoxic environment was associated with improvements in physical performance (7). Oxidative stress generated during CoCl2 administration is involved in nociceptive processing (19), and may also lead to adaptive processes that subsequently protect against PIPN. Furthermore, a recent study suggests that HIF activity in itself protects against thermal pain (21). Taking into account the fact that ischemia is known to play a part in other types of neuropathy, such as diabetic (22) or optic (23), adapting

to hypoxia may be involved in PIPN pathogenesis.

CONCLUSIONS

CoCl2 preconditioning protects against PIPN. Although CoCl2 administration had an initial hyperalgesic affect, subsequent PXT treatment did not lead to persistent thermal and mechanical allodynia. By contrast, mice that were not preconditioned and were treated with PXT alone experienced intense and persistent allodynia for both thermal and mechanical stimuli. Further studies are required for establishing the exact relationship between CoCl2 and PIPN.

NEWS

POSSIBLE IMPLICATIONS OF NI ON ORAL IL-1B-INDUCED INFLAMMATORY PROCESSES

Nickel (Ni) is one of the main metal elements in orthodontic and prosthetic devices. Different effects of Ni are described ranging from an induction of local inflammation to allergy and cancerous/mutagenic properties. Inflammatory reactions are frequently observed in the oral cavity, but the interrelationship of Ni with those events is still unknown. The authors carried out an in vitro study to annlyze the impact of Ni on inflammation processes. Human gingival fibroblasts (HGFs) ($n = 6$) were exposed to a pro-inflammatory environment using interleukin-1 beta (IL-1β) and additionally stimulated with different Ni(II) concentrations (400 and 4000 ng/ml). At varying time points the expression of pro- and anti-inflammatory as well as matrix degeneration proteins, i.e. MMPs, were analyzed. Proliferation assays, wound healing tests and the detection of NF-κB activation were conducted. Unstimulated HGFs served as control. The experiments showed that low clinical average Ni(II) levels did not alter pro-inflammatory cytokines significantly compared to control ($p > 0.05$). Instead, a 10-fold higher dose up-regulated these mediators significantly in a time-dependent manner ($p < 0.01$). This was even more pronounced combining both Ni(II) concentrations with an inflammatory condition ($p < 0.001$). The mRNA data were supported by proliferation and wound closure assays ($p < 0.001$). However, the combination of both stimuli induced contradictory results. Analyzing NF-κB activation revealed that the results may be in part attributed to NF-κB. The authors of this study suggested that Ni(II) has various modifying effects on IL-1β-induced inflammatory processes depending on the concentration (Lina Gölz, Stefan Bayer, Ludger Keilig, Andreas Jäger, Helmut Stark, Christoph Bourauel, Werner Götz, Stilla Frede, Jochen Winter, Dominik Kraus. Possible implications of Ni(II) on oral IL-1β-induced inflammatory processes. *Dental Materials* 2014; 30(12):1325-1335).

CLINICO-EPIDEMIOLOGICAL STUDY OF ENDOMETRIAL HYPERPLASIA – A RISK FACTOR FOR THE DEVELOPMENT OF ENDOMETRIAL CARCINOMA? (Abstract): **Aim:** Metaplasia is defined as a transformation of an adult epithelial or conjunctive cellular type into another adult cellular type. Endometrial hyperplasia and particularly complex atypical hyperplasia exposes to a high risk of development of the endometrial carcinoma, being considered a lesion precursory to the same. Endometrial hyperplasias are risk factors for the development of endometrial carcinoma and their prophylaxis implies their accurate diagnosis, taking into account that the adenocarcinomas diagnosed in an advanced stage, whose therapeutic context differs from the early stages, have a much lower chance of survival. **Material and methods:** Our study aimed at highlighting objective criteria in establishing the morphological diagnosis and in evaluating the prognostic elements. The studied batch included 875 patients with endometrial hyperplasia and 263 patients with endometrial adenocarcinoma, who were admitted between 2003 and 2007, and the histopathologic diagnosis was obtained by processing the hysterectomy pieces. The presence of this tumour was at its highest level half-way through the study, which was in 2005. **Results:** According to the study, there was a higher proportion of patients with endometrial carcinoma from the urban environment (58.2%) than the ones from the rural environment (only 41.8%). Depending on their age, most cases of endometrial adenocarcinoma were diagnosed in 53-year old patients, with an average age of 58.94 years. Our study, made of the two batches of endometrial adenocarcinomas, shows that between the endometrial and non-endometrial adenocarcinoma there are significant differences related to the patients' age, the morphological aspect of the carcinoma, the architectural degree, the nuclear degree of tumours and the invasion in the myometrium. **Conclusions:** Our study proves that endometrial hyperplasia is a frequent diagnosis in peri- and postmenopausal patients and is frequently identified following investigations for an abnormal uterine bleeding. The age of patients with endometrial carcinoma is an important prognostic factor independent of other parameters. The difference between complex hyperplasia with no atypias and complex hyperplasia with atypias is important, because atypical complex hyperplasia is considered the precursor of endometrial adenocarcinoma. **Keywords:** ENDOMETRIAL HYPERPLASIA, ENDOMETRIAL ADENOCARCINOMA, ENDOMETRIAL CANCER, MYOMETRIUM INVASION.

We witness a world-wide increase in the incidence of corpus uteri tumours. Endometrial carcinoma is one of the most frequent invasive neoplasms, developed in the genital tract.

Endometrial hyperplasia and particular-

ly atypical complex hyperplasia runs a high risk of malignifying and is considered a lesion precursory to endometrial adenocarcinoma.

The current possibilities of diagnosing the endometrial carcinoma in early stage do not allow the identification of all cases.

According to international statistics, the cases of endometrial carcinoma identified early can benefit from a less aggressive treatment with encouraging results for the patients.

In the current gynecological practice, numerous uterine lesions appear that can be associated with abnormal uterine bleeding.

As regards uterine haemorrhages, the morphologic sublayer most frequently found is endometrial hyperplasia and endometrial carcinoma.

Endometrial hyperplasias are risk factors for the development of endometrial carcinoma and their prophylaxis implies their accurate diagnosis.

The *treatment* of patients with endometrial hyperplasia must consider the patient's age and the type of hyperplasia.

In patients under 40, a conservative medicamental treatment is recommended, as well as periodical biopsic check-up, as these patients have a low risk of developing atypical hyperplasia or endometrial carcinoma.

As regards atypical hyperplasia that is diagnosed through biopsy, a uterine curettage is indicated to exclude an endometrial carcinoma. Patients who want to maintain their fertility, in case of atypical hyperplasia, are treated with hormones and are monitored periodically through endometrial biopsy. The treatment is surgical if the diagnosis is carcinoma.

In perimenopausal patients without risk factors for endometrial carcinoma, monitoring is recommended, and in perimenopausal patients with risk factors, endometrial biopsy is recommended. In patients with atypical hyperplasia, hormonal treatment or hysterectomy is recommended. The risk of becoming a carcinoma is lower in perimenopausal patients than in postmenopausal patients. During hormonal treatment, endometrial biopsy is recommended every three months.

In postmenopausal patients over 55 years old, in case of abnormal uterine bleeding, endometrial biopsy and fractionated curettage are recommended. This evaluation of the endometrium is recommended because postmenopausal patients run a high risk of atypical hyperplasia and endometrial carcinoma.

In metaplastic papillary hyperplasia, the treatment consists of polypectomy or curettage. Hysterectomy is advised if the patient is postmenopausal and the lesion is extended. Metaplastic papillary hyperplasia runs a high risk of turning into endometrial carcinoma.

We are facing a large number of endometrial carcinomas, diagnosed in an advanced stage, whose therapeutic context differs from the early stages and whose chance of survival is much reduced.

In this context, we intended a clinical-morphological study of endometrial hyperplasias and endometrial carcinoma, with the purpose of establishing a clinical-pathological correlation between the two lesions and of elaborating a correct diagnosis, with a view to evaluating the prognostics of these cases.

This study was performed on a representative batch of patients, which included 875 endometrial hyperplasias and 263 endometrial carcinomas, manifested clinically through abnormal uterine haemorrhage.

MATERIAL AND METHODS

The analysed batch included 875 patients with endometrial hyperplasia and 263 patients with endometrial adenocarcinoma. They were admitted between 2003 and 2007 in "Cuza Vodă" Obstetrics and Gynecology Clinical Hospital of Iaşi.

The histopathologic diagnosis was obtained by processing the hysterectomy pieces.

The classification divides hyperplasias into two categories – simple and complex – each having two sub-categories, represented by hyperplasias with atypias and without atypias.

The 875 patients with endometrial hyperplasia were admitted for dysfunctional haemorrhages, uterine fibroid, premenopause and postmenopause haemorrhages.

Of the 875 patients, 739 had simple hyperplasia, 14 complex hyperplasia without atypias, 8 complex hyperplasia with atypias, 93 simple hyperplasia associated with complex hyperplasia without atypias, 21 simple hyperplasia associated with complex hyperplasia with atypias.

Even if the number of admitted cases operated for different gynaecological conditions increased in "Cuza Vodă" Hospital of Iaşi between 2003 and 2007, this was not the case for endometrial carcinoma. The presence of this tumour was at its highest level half-way through the study period, which was in 2005 (77 cases of the total cases of 1,813 surgical interventions, namely 29.3%), and values twice as low being registered in 2003 (36 cases) and 2007 (37 cases).

As a matter of fact, endometrial adenocarcinoma is only 2.87% of the total of 9,100 gynecological conditions, which needed surgery.

RESULTS

In the performed study, we observed a higher proportion of patients with endometrial carcinoma from the urban environment (58.2%) than the ones from the rural environment (only 41.8%).

Our study revealed that the average age of the patients diagnosed with endometrial carcinoma is of 58.94 years (58.94+/-8.194 years).

Of the total number of patients included in the study, 25% are between 33 and 53 years old. And half of them (percentile 50) are up to 58 years old.

Most cases of endometrial adenocarcinoma in our study were 53-year old patients (modal or dominating value).

In our study, 117 patients were at least 50 years old, which means 44.48% of the cases diagnosed with endometrial adenocarcinoma. Of the 263 patients, 242 (namely 92% of the total number) were menopausal.

The results of the study showed that abnormal uterine bleeding was present in all the 263 cases, as a singular symptom or associated with pelvic pain.

Abnormal uterine bleeding was reported in 67.7% of the cases (representing 178 patients) and the association of this main symptom with pelvic pain was found in 32.3% of the cases (representing 85 patients).

The pathological history was divided into two main categories. The first category refers to the non-gynecological pathological history and the second category to the gynaecological history. Patients who mentioned non-gynecological conditions in their history are 14.45% (38 patients) and the ones who suffered from gynecological conditions represent 42.20% of the total cases (111 patients).

From the point of view of the morphological aspects in endometrial adenocarcinomas in our study batch, of the 263 cases of endometrial adenocarcinomas, in 177 cases the coexistence of hyperplastic or atrophic changes in the endometrium adjacent to adenocarcinomas was reported, in relation with whom these tumours developed. Adenocarcinomas were divided into two batches.

Batch X included 39 patients (14.82%) with endometrial adenocarcinomas associated with hyperplasia, and batch Y of 138 cases (52.47%) with adenocarcinomas developed on an atrophic endometrium. In 86 cases (32.7 %), no hyperplastic or atrophic aspects of the endometrium were identified.

The histopathological diagnosis was established on histological sections of the surgically resected pieces. In all cases, the histological grading and the myometrium invasion were established.

Batch X is represented by patients between 40 and 60 years old, with an average of 49.9 years. There were two patients under 40, 14 patients were between 40 and 49 years old, 10 patients between 50 and 49 and 6 patients with ages of at least 60 years.

In batch X, the following cases were identified microscopically: 22 endometrioid adenocarcinomas without squamous metaplasia and 10 endometrioid adenocarcinomas with squamous metaplasia, of which 7 endomerioid adenocarcinomas with benign squamous metaplasia (adenoacanthoma) and 3 endometrioid adenocarcinomas with malignant squamous metaplasia (adenosquamous endometrioid carcinoma) and 7 secretive endometrioid adenocarcinomas. All the 39 cases of endometrioid adenocarcinomas developed in patients with endometrial hyperplasia.

In grading the endometrioid adenocarcinomas, we used the FIGO grading system, based on which we evaluated the architectural aspect of the tumour correlated with the microscopic nuclear grading system. According to the grading system based on the architectural criterion, endometrioid adenocarcinomas in batch X had 3 malignity degrees. 24 cases belonged to the 1st degree of architectural malignity, 5 cases to the 2nd degree and 3 cases to the 3rd degree.

Endometrioid adenocarcinomas with a low degree of malignity – 1st degree – are characterized by a predominating glandular aspect, with delimited edges and absence of necrosis. They have a solid tumour growth, up to 5% of the tumour volume. Moderately differentiated 2nd degree endometrioid adenocarcinomas have a solid tumour growth, between 6 and 50% of the tumour volume. Adenocarcinomas of high malignity degree – 3rd degree – have a solid architectural aspect, infiltrated tumour edges and tumour necrosis areas in over 50% of the tumour volume.

Microscopic nuclear grading was measured based on cytological criteria represented by nuclear pleomorphism, the size of nuclei, prominent nucleoli and the chromatin aspect.

In the analysed study batch, 24 endometrioid adenocarcinomas were classified as belonging to the 1st degree of nuclear malignity, 5 adenocarcinomas to the 2nd degree and 3 adenocarcinomas to the 3rd degree of nuclear malignity.

The myometrium invasion in 28 cases of endometrioid adenocarcinomas from Batch X was in less than 50% of the myometrium thickness and only in 4 cases it was in more than 50% of its thickness.

Batch Y included patients between 50 and 80 years old, with the age average of 63.34 years. There was one patient under 50, 44 patients were between 50 and 59 years old, 71 patients were between 60 and 69

years old, 28 patients were between 70 and 79 years old, and one 80-year old patient.

In batch Y, the following cases were identified microscopically: 138 cases of endometrial adenocarcinomas developed on an atrophic endometrium. Of these, 12 were endometrioid adenocarcinomas with or without squamous metaplasia, 49 were serous adenocarcinomas, 36 were clear cell endometrial adenocarcinomas, 9 were mucinous endometrial adenocarcinomas, 2 were squamous endometrial adenocarcinomas and 30 were mixed endometrial adenocarcinomas.

As regards the myometrium invasion, in 34 cases of endometrial adenocarcinomas of the 2nd group, it was in less than 50% of the myometrium thickness and in 111 cases in over 50% of its thickness.

86 cases (32.7 %) of endometrial adenocarcinomas in which the hyperplasia or atrophy of the endometrium near the tumours was not identified show microscopically aspects of endometrioid adenocarcinomas. They are represented by 49 well differentiated endometrioid adenocarcinomas, 27 moderately differentiated endometrioid adenocarcinomas and 10 cases of poorly differentiated endometrioid adenocarcinomas.

Our study, made of the two batches of endometrial adenocarcinomas, shows that between the endometrioid adenocarcinoma and the non-endometrioid adenocarcinoma there are significant differences as regards the patients' age, the morphological aspects of the carcinomas, the architectural degree, the nuclear degree of tumours and the invasion in the myometrium.

The value of the endovaginal ultrasound examination is relevant in the diagnosis of carcinomas. In the 263 patients, the local vaginal examination combined with abdominal palpation and correlated with endovaginal ultrasound established the uterus size.

In 205 cases (77.95%), the uterus was normally sized – between 4 and 6 cm – in 27 cases (10.27%) it was enlarged – over 6 cm –, and in 31 cases (11.78%) it had reduced sizes, of less than 4 cm.

In 249 (94.68%) patients with endometrial carcinoma in our study, the thickness of the uterus established by the endovaginal ultrasound was of 15 mm on average, with limits between 5 and 65 mm. In 14 patients (5.32%) with endometrial carcinoma, the thickness of the uterus established by the endovaginal ultrasound was under 5 mm, with values between 2 mm and 4.5 mm.

The observation charts of the 14 patients were examined in detail with regard to their history, clinical signs, menopausal status and if they had uterine curettages done within 3 months immediately before the endovaginal ultrasound. All patients were on menopause, with ages between 60 and 69 years, and the histopathologic examination identified different types of endometrial carcinomas.

In all 14 cases uterine curettage had been performed before the endovaginal ultrasound, less than 3 months before.

DISCUTION

The clinical and morphological study of the 875 endometrial hyperplasia cases and 263 endometrial adenocarcinoma cases under study reveals a few aspects that need to be highlighted and discussed in the light of the recent data in the specialized literature.

Our study proves that endometrial hyperplasia is a frequent diagnosis in peri- and postmenopausal patients, it is frequently identified following investigations for abnormal uterine bleeding, which are as-

pects that need to be taken into account by the gynecologist in routine consults.

In the studied batch, 84.45 % of the cases were normal hyperplasia, 1.60% complex hyperplasia without atypias, 0.94% complex hyperplasia with atypias, 10.62% simple hyperplasia associated with complex hyperplasia with atypias.

The study reveals that in the several types of hyperplasia can be associated in the endometrium, which we found in 114 cases.

The largest number of hyperplasia cases in our study batch was represented by simple hyperplasia (739 cases, 84.45%) and there was no case of simple hyperplasia with atypias.

The age of patients with endometrial carcinoma is an important prognostic factor independent of other parameters. The highest proportion – 29.3% (77 cases) – is seen in patients over 65 years old. In patients younger than 50 years old, the proportion was of 6.84% of the cases. Endometrial adenocarcinoma is a rear malignant tumour in Caucasian women under 40, but its incidence is gradually growing after menopause and reaches a maximum between 70 and 79 years of age. In women of the black race, the maximum incidence of endometrial adenocarcinoma is signalled in perimenopause, with a rate of 85 cases in 100,000 women annually.

Abnormal uterine bleeding associated in some cases with pelvic pain represented the main symptom for which patients came in for medical check-up and specialized investigation, in all the patients in our study batch.

The normal endometrium is under 5 mm thick in post-menopause and its limits must be regular and visible in the entire uterine cavity.

In interpreting the endometrium thickness, in our statistics we considered the literature data, which show that the endometrium that is thicker than 5 mm in postmenopause is associated with high probability of the existence of hyperplasia or endometrial carcinoma, and any focal lesion of the endometrium, identified in endovaginal ultrasound needs endometrial biopsy, regardless of the endometrium thickness.

Most carcinomas developed in patients with abnormal uterine lesions in postmenopause had a focal growth pattern. In focal lesions in the endometrium, the hysteroscopic resection is superior to uterine curettage in obtaining representative endometrium fragments.

Our results confirm the data in the specialized literature, which show that in postmonopausal patients an endometrial carcinoma can be associated with an endometrium thinner than 5 mm.

Nevertheless, the cases published in literature are rare. Only 14 authors that reported cases of endometrial adenocarcinomas in postmenopausal patients, where endovaginal ultrasound showed the endometrium thickness under 5 mm.

In postmenopause any focal thickening noticed or even suspected in endovaginal ultrasound must be considered pathological.

The evaluation of the endometrium thickness by endovaginal ultrasound is a current investigation method in the diagnosis of endometrial lesions and plays an important role in the screening of endometrial adenocarcinoma. Endovaginal ultrasound can reveal in over 90% of the cases the existence of a postmenopausal proliferative endometrium lesion if the endometrium thickness is over 5 mm.

If an endometrium thinner than 5 mm with regular aspect is visualized in endo-

vaginal ultrasound in patients with high risk or abnormal uterine bleedings, the clinician must perform uterine curettage for the histopathological diagnosis.

The pulsed Doppler endovaginal ultrasound identifies the presence of endometrial adenocarcinoma accurately, which determined the reduction of false positive results.

Our study supports the literature data regarding the fact that well differentiated and moderately differentiated endometrial adenocarcinomas generally invade the myometrium under 50% of its thickness. The myometrium invasion in 28 cases of endometrioid adenocarcinomas in batch X was in less than 50% of the myometrium thickness and only in 4 cases it was in over 50% of its thickness. The myometrium invasion in 34 endometrial adenocarcinoma cases in batch Y was in less than 50% of the myometrium thickness, and in 111 cases in over 50% of its thickness.

The studies published in literature mention that the tumour infiltration of the myometrium is associated with an unfavourable prognostic. Adenocarcinomas limited only to the endometrial mucous have a rate of survival of over 95% in 5 years.

CONCLUSIONS

The management of patients with endometrial hyperplasia and endometrial carcinomas is complex. Our study emphasized the importance of multidisciplinary approach, with the involvement of gynaecologists, anatomopathologists, immunologists and oncologists in the diagnosis and therapy of these lesions for the increase in the survival rate of patients.

The study suggests the supervision of cases of endometrial hyperplasia, especially if they are associated with risk factors incriminated in the etiology of corpus uteri carcinoma.

The clinical, histopathological, immuno-histochemical and prognostic aspects of certain representative batches of endometrial hyperplasia and endometrial adenocarcinomas were evaluated.

Endometrial hyperplasia and endometrial carcinomas appear frequently in peri- and postmenopause and are associated with abnormal uterine hemorrhages, which impose a full evaluation by the gynecologist.

Endometrial adenocarcinomas are under two forms represented by type I or endometrioid adenocarcinoma and type II or non-endometrioid adenocarcinoma, with differences regarding epidemiology, morphological aspect and evolution between them.

Endometrioid adenocarcinoma develops in young patients, on a hyperplastic endometrium, in a hyperestrogenic context, it is well differentiated microscopically, with little invasion in the myometrium, without tumour emboli in lymphatic vessels and with favourable prognostic, and non-endometrioid adenocarcinoma develops in postmenopausal patients on an atrophic endometrium, with high malignity degree, invasive in the myometrium and in the lymphatic vessels and with a reserved prognostic.

Complex atypical hyperplasia is a precursor only to endometrioid adenocarcinomas, as all the other microscopic variants of adenocarcinoma develop on an atrophic endometrium.

Endovaginal ultrasound can guide the diagnosis in very many cases to the existence of endometrial hyperplasia and endometrial carcinoma in peri- and postmenopause, if the endometrium is over 5 mm thick.

When an endometrium thinner than 5 mm with regular aspect is visualized in endovaginal ultrasound in peri- and post-

menopausal patients with high risk and abnormal uterine bleedings, who had a biopsy performed less than 3 months before, the clinician must perform uterine curettage for the histopathological diagnosis and to exclude endometrial carcinoma.

PERSONALITY TRAITS RELATED TO CHIPS CONSUMPTION: A CASE-CONTROL STUDY IN ADOLESCENTS FROM ROMANIA (Abstract): In this study it is investigated whether there is a relation between personality traits of adolescents and consumption of chips. **Material:** The study was performed on 2 groups of adolescents: a study group – 248 adolescent (43.1% male and 56.9% female) who consume chips two or more times/day and a control group – 481 adolescent (51% male and 49% female) who do not consume chips at all. Case-control samples were selected from 2908 teenagers. **Method:** The method was case-control observational inquiry and consisted in applying 2 questionnaires: Freiburg Personality Inventory (Cronbach`s alpha=0.802) and CORT (Cronbach`s alpha =0.910) from which it was extracted 1 item Q107 (frequency of chips consumption). **Results:** The personality profile of the study group is different from the personality profile of the control group; significant statistical differences (Significance=0.000) between the group of study and the control group for nervousness (chi square - χ^2=22.516), aggressiveness (χ^2=22.877), excitability (χ^2=27.132), domination (χ^2=21.152) and extraversion (χ^2=9.770) were found. **Conclusion:** The results suggest a relation between personality traits of adolescents and consumption of chips. **Keywords:** CHIPS, PERSONALITY, ADOLESCENTS, OBSERVATIONAL STUDY.

Teenage is a developmental stage in human life when integration is followed by recycling that lasts for the rest of the life (1). Consumption of potato chips tends to increase with the progress in technology (2). Being addictive (3), chips consumption is a diet risk behavior in adolescence. The aim of the performed study was to investigate whether personality traits of adolescents relate to the excessive consumption of chips.

MATERIAL AND METHOD

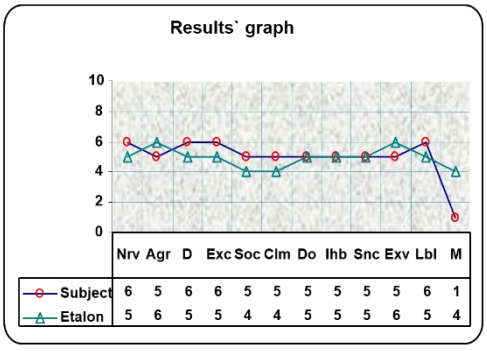
This study was performed on sample of 2908 teenagers (51.5% females, 48.5% males, aged 15-19 years) provided by an urban area in south-western Romania. The ethical approval of the University Ethical Committee was asked for and obtained. The study conducted was a case-control observational inquiry and it consisted in applying 2 questionnaires: CORT questionnaire ("**Co**mportamente cu **r**isc la **t**ineri"–"Risk behaviors in young people" - 126 items of risk behaviors with Cronbach`s alpha index=0.910) (4), and FPI (Freiburg Personality Inventory - 212 items with Cronbach`s alpha index=0.802,

normalized for the Romanian population) (5). From CORT questionnaire it was considered only item Q107, referring to chips consumption as diet risk behavior. Item Q107: "How many times per week do you consume chips?" had 5 possible answers depending on the level of risk. For the study the groups with risk 0 (control – 481 adolescents who do not consume at all chips; 51% females, 49% males) and risk 4 (case – 248 adolescents who consume 2 or more times/day chips; 57% females, 43% males) were chosen. Personality bipolar traits measured by Freiburg Personality Inventory consisted in Nervousness (Nrv), Aggressiveness (Agr), Depression (D), Excitability (Exc), Sociability (Soc), Calm (Clm), Domination (Do), Inhibition (Inh), Sincerity (Snc), Extraversion (Exv), Emotional lability (Lbl). Masculinity (M) was not taken into consideration due to the risk of misinterpreting this trait by Excel 2003 Program. Both questionnaires were applied individually and anonymously, in the same 1 hour and a half session. The informed consent of each student to participate was asked for and obtained. A personality profile was built by an Excel 2003 Program considering the median frequency value of the intensity of all the 9 ranks of each personality dimension. This personality profile could be compared with the etalon (profile established and standardized for the adult Romanian population). The personality traits of the 2 groups of teenagers for chips consumption (Q107=0 and Q107=4) were analyzed and compared. The Body Mass Index (BMI) was considered for the group of study and for the control group.

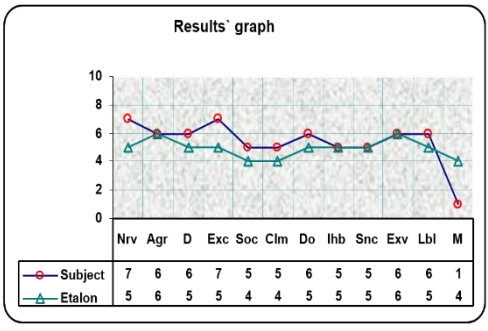
Statistical work (Chi square–χ^2 and gamma correlation- γ) was performed using a *SPSS Statistics 20*.

RESULTS

The established personality profiles of adolescents considering the median value of frequency for the control-group and the study-group were different.



Q107=0



Q107=4

Fig. 1. Personality profiles of control-group (Q107=0) and study-group (Q107=4)

The study-group has 5 personality traits (Nrv, Agr, Exc, Do and Exv) with higher intensity than the control-group. In the profile of the study-group 2 personality traits (Nrv and Exc) were outside the etalon interval (4-6) with the registered ranks=7. All the personality traits for the control-group were included in the etalon interval (4-6) (fig. 1).

The 9 intensity ranks of the personality

traits reduced to 3 (1=1-3 -low intensity; 2=4-6 -the average or etalon interval and 3=7-9 -high intensity of the trait) offered the possibility of applying Chi square. A significant statistical difference between the control-group (adolescents with no consumption of chips) and the study-group (adolescents with high level consumption of chips) was registered for certain personality traits (Nrv, Agr, Exc, Do, Exv) after applying Chi square (tab. I). The calculated gamma correlation coefficients indicated positive correlations: Q107-Nrv, Q107-Agr, Q107-Exc, Q107-Do and Q107-Exv (tab. II).

TABLE I

Chi square test Q107 (0 and 4) - personality traits

Chi-Square – χ^2	Value	*df*	Asymptotic Significance (2-sided)
Q107 * Nrv	22.518[a]	2	0.000
Q107 * Agr	20.877[a]	2	0.000
Q107 * Exc	27.132[a]	2	0.000
Q107 * Do	21.152[a]	2	0.000
Q107 * Exv	9.770[a]	2	0.008

Note. a. 0 cells (0%) have expected count less than 5. The minimum expected counts are 24.97 (q107 * Nrv), 25.38 (q107 * Agr), 24.03 (q107 * Exc), 27.75 (q107 * Do) and 29.78 (q107 * Exv).

TABLE II

Gamma (γ) correlation Q107 (0 and 4) - personality traits

Ordinal by Ordinal Correlations	γ	Asymptotic Standard Error[a]	Approx Sig.
Q107 * Nrv	0.352	0.069	0.000
Q107 * Agr	0.328	0.068	0.000
Q107 * Exc	0.363	0.066	0.000
Q107 * Do	0.332	0.067	0.000
Q107 * Exv	0.233	0.076	0.003

Note. a. Not assuming the null hypothesis;
b. Using the asymptotic standard error assuming the null hypothesis.

Nervousness was the only personality trait which registered a weak statistically significant difference between females and males ($\chi^2 = 7.869$, Significance = 0.02, γ = -0.357, Significance = 0.005). No significant statistical difference and no γ correlation between females and males were registered for other traits of the personality profile. There was also no statistically significant difference of personality profile depending on age or BMI.

DISCUSSION

The results of this study are consistent with recent studies and appear to complement previous results. Recent studies supported the hypothesis that personality can affect dietary intake (6, 7). A result of the study conducted (personality profile and statistically significant difference between

case-control groups) was that adolescents who had high chips consumption also had high spontaneous aggressiveness (Agr) and reactive aggressiveness (Do), reduced tolerance to frustration (increased Exc) and increased somatic-affective resonance (Nrv) and extraversion (Exv). Nervousness and excitability were clearly excessive and were outside the etalon interval (ranks 7) in the study-group profile. Another study demonstrates that personality traits (neuroticism, extraversion, openness, agreeableness, and conscientiousness) are associated with dietary intake. These associations were stronger in female than male subjects (8). In the performed study, only nervousness was higher -with weak statistical significance- in the female than the male subjects. In the conducted study, the high level of excitability (reduced tolerance to frustration) found in the study-group (females and males) involves increased reaction to a stimulus and a feeling of stress. In other research study on this topic, 33% of the subjects answered that they consumed higher amounts of chips when they are under stress (9). A limitation of this study is that it is an observational one and it approaches qualitative aspects only.

CONCLUSIONS

The study conducted demonstrates a specific personality profile of the population of adolescents with excessive chips consumption and it suggests a relation of certain personality traits with chips consumption behavior.

AKNOWLEDGMENTS

The author would like to thank Prof. Dr. Brigitha Vlaicu, for the support offer with the database.

CLINICAL-EPIDEMIOLOGICAL STUDY ON THE INCIDENCE OF POSTOPERATIVE COMPLICATIONS AFTER PULMONARY RESECTION FOR LUNG CANCER (Abstract): **Aim:** To determine the relationship between the characteristics of a group of lung cancer patients, lung cancer surgeries, and the incidence of early and/or late postoperative complications. **Material and methods:** The study included a group of 115 lung cancer patients aged 40 to 85 years, 76.5% men, 60.91% living in urban areas, who received surgical treatment in the interval January 2013-August 2014. Data were collected from electronic medical records and survey sheets and processed and interpreted using Pearson correlation index (p-value of 0.05 was considered statistically significant and of <0.005 highly statistically significant), and chi^2, y, 1c = 25% tests. All statistical analyses were performed using the SPSS statistical software package version 13.0. **Results**: Of the 115 patients 7.8% were in the 40 -50 years age group and 87.8% in the 51-75 years age group ($p \leq 0.001$). Most patients were males (76.5%, p <0.001), and 60.9% of the patients were living in urban areas ($p \leq 0.05$). The difference in the prevalence of smokers (76.5%) *vs.* non smokers (23.5%) was highly statistically significant (p <0.005). Active smoking of one pack of cigarettes per day for more than 10 years was recorded in 54.8%. The presence of co morbidities (17 events) and the distribution of neoplastic lesions in the five anatomical areas required the performance of lobectomies, bilobectomies or pneumectomies. The incidence of early (14 entities) and late postoperative complications (7 entities) depended on patient's general condition, nature of co morbidities, location and stage of neoplastic lesions, and surgical complexity. **Conclusions**: Lung cancer, in various locations and stages, most commonly affected males aged 40-85 years, from urban areas, smokers, with various co morbidities. Surgeries performed in these patients were often laborious and with a relatively low incidence of postoperative complications. **Keywords**: LUNG CANCER, CANCER SURGERY, CO MORBIDITIES, POSTOPERATIVE COMPLICATIONS.

It has been long recognized that surgery has an important role in healing when the cancer is located in the organ of origin (1, 2). In the case of late interventions, with risks of metastasis, surgery has to be associated with other therapeutic procedures. Thus, curative surgery, radical or conservative, may be replaced with a tumor size reduction surgery, removal of metastases or palliative or reconstructive and rehabilitation surgery (3, 4, 5).

Because in practice about two thirds of

cancer patients present with advanced disease oncologic surgery has to be part of a multimodal approach associating depending on circumstances various pre- and postoperative adjuvant therapies (6,7,8).

Depending on patient's general condition, malignant disease stage, anatomic location and histological type, surgical procedures are associated with or followed by various complications with minor or alarming implications that require the surgeon and the multidisciplinary team to consider how treatment might affect patient's quality of life (9, 10, 11).

MATERIAL AND METHODS

The study included a group of 115 lung cancer patients, aged 40-85 years, 88 (76.5%) males and 27 (23.5%) females, 70 (60.9%) from urban areas and 45 (39.1%) from rural areas, who underwent surgery (lobectomy + bilobectomy: 77.8% and pneumonectomy: 25.2%) in the interval January 2013 - August 2014 at the IInd Surgical Clinic, Department of Cardiac and Thoracic Surgery of the Iași Regional Cancer Institute.

Data were collected from electronic medical records and survey sheets and processed and interpreted using Pearson correlation index (*p*-value of 0.05 was considered statistically significant and of <0.005 highly statistically significant), and chi^2, y, 1c = 25% tests. All statistical analyses were performed using the SPSS statistical software package version 13.0.

RESULTS AND DISCUSSION

Age distribution of the 115 lung cancer patients who received surgical therapy showed that 7.8% were in the 40-50 year age group, 4.3% in the 76-85 year age group (significant difference: p≥0.05) compared to 87.8% in the 51-75 year age groups (very highly significant difference compared to the previous ones, p <0.001) (tab. I, fig. I).

TABLE I
Age group distribution of the study patients

Age group	No.	%	Cumulative percentage
40 – 45	3	2.6	7.8%
46 – 50	6	5.2	
51 – 55	12	10.4	87.8%
56 - 60	20	17.4	
61 - 65	28	24.3	
66 – 70	23	20.0	
71 – 75	18	15.6	
76 - 80	4	3.5	4.3%
81 - 85	1	0.9	
Total	115	100.0	-

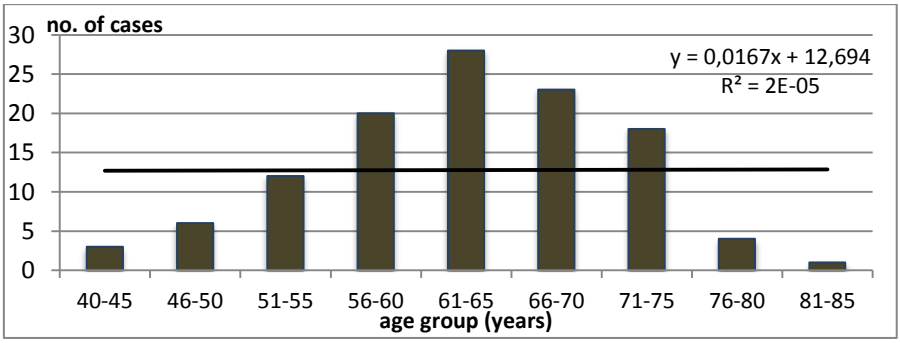

Fig. 1. Age group distribution of the surgically treated lung cancer patients

Sex distribution showed highly significant differences ($p<0.001$) in favor of males (76.5% males and 23.5% females).

Urban-rural distribution showed that 60.9% of patients lived in urban areas compared 39.1% in rural areas ($p \leq 0.05$).

The intensity and duration of smoking proved to be a major risk factor for lung carcinogenesis.

Eighty-eight (76.5%) of the 115 study patients were **active smokers,** of which 54.8% smoked one pack of cigarettes per day, 52.2% for over 10 years, and 20.9% smoked 2 packs per day for more than 10 years. The difference between the prevalence of smokers (76.5%) and nonsmokers (23.5%) was highly statistically significant ($p <0.005$) with the mention that the 27 (23.5%) non smokers reported: intensive long-term exposure to passive smoking (19: 70.3%); construction work, inhalation of dust and particles (6: 22.2%) to which a miner and a carpenter (3.7% each) were added (tab. II).

TABLE II

Assessment of the intensity and duration of smoking in the 115 lung cancer study patients

Intensity (no. packs cigarettes/day)			**Duration (years)**			
			<10		**>10**	
Packs/ day	No. cases	%	No. cases	%	No. cases	%
1	63	54.8	3	2.6	60	52.2
2	24	20.9	5	4.3	19	16.6
≥3	1	0.9	-	-	1	0.9

Note: active smokers: 88 (76.5%); nonsmokers: 27 (23.5%); passive smokers: 19 (70.3%); constructors: 6 (22.2%); miners: 1 (3.7%); carpenters: 1 (3.7%).

Types of surgery and postoperative course depended on the presence of co morbidities, often with associative action in the same patient (12). In the 115 patients included in the study we identified 17 categories of co morbidity with variable frequency from 33.9% for hypertension, to 8.7% and 7.8% for heart failure, tuberculosis, anemia, and type 2 diabetes mellitus.

Two patients (1.7%) presented synchronous lung cancer and 6 (5.2%) metachronous cancer (rectum: 2; skin: 2; breast, ENT, 1 case) (tab. III).

The distribution of neoplastic lesions in the 5 anatomic areas showed that the most common location was in the right upper lobe (37.4%) followed by the left upper lobe (29.5%) and right lower lobe (16.5%). The incidence decreased to 8.7% for the left lower lobe and 7.9% for the right middle lobe (tab. IV, fig. 2).

The types of surgery (lobectomy, bilobectomy, or pneumonectomy) depended on the location and stage of the tumor (13). Right upper lobectomy was performed in 27% of the 115 cases, followed by left upper lobectomy and left pneumon-ectomy in 14.8% and 14.0%, respectively. Right lower lobectomy, right pneumon-ectomy and left lower lobectomy were performed in 12.1%, 11.3% and 10.4% of the cases. Middle lower bilobectomy and right middle

lobectomy were performed in a similar number of cases (6/5.2%). Thus, lobectomy and bilobectomy were performed in 86 (77.8%) and pneumonectomy in 27 (25.2%) of the 115 patients, with a moderately significant difference ($p \leq 0.05$) (tab.V).

TABLE III

Frequency of complications in our study group

No.	Comorbidity	No. cases	%
1.	Hypertension	39	33.9
2.	Heart failure	10	8.7
3.	Tuberculosis	9	7.8
4.	Anemia	9	7.8
5.	Type 2 diabetes mellitus	9	7.8

8.	Right middle lobe	6	5,2
9.	Total lobectomy+bilobectomty	86	77,8
10.	Total pneumonectomy	29	25,2

Postoperative complications (14 entities) showed a variable dispersion and resulted from numerous factors related to patient's general condition, nature of co morbidities, location and stage of cancer lesions and surgical complexity (14, 15).

Of the early complications the following had an incidence of 6 to 11.3%: subcutaneous emphysema, atrial fibrillation, lung expansion defects and lobar or segmental atelectasis. An incidence of 2.5 to 4.3% was recorded for nosocomial pneumonia, multiple organ dysfunctions, including cardio respiratory arrest, recurrent nerve paralysis and anemia. Cardiac arrhythmias, prolonged air leak, hemorrhage, ischemic stroke, acute respiratory failure and myocardial infarction were reported in 0.8 to

1.7% of the cases.

Late postoperative complications showed a relatively low incidence (0.8 to 4.3%) and were represented by: postoperative empyema, bronchial stump fistula, pleurisy, pulmonary embolism, pneumothorax, bronchopneumonia and sepsis (tab. VI).

TABLE VI

Postoperative complications

A. Early

No.	Complication	No. of cases	%
1.	Subcutaneous emphysema	13	11.3
2.	Atrial fibrillation	8	6.9
3.	Lung expansions defects	7	6.0
4.	Lobar or segmental atelectasis	7	6.0
5.	Nosocomial pneumonia	5	4.3
6.	Multiple organ dysfunctions with cardio respiratory arrest	5	4.3
7.	Recurrent nerve paralysis	4	3.5
8.	Anemia	3	2.6
9.	Cardiac arrhythmia	2	1.7
10.	Prolonged air leak	2	1.7
11.	Hemorrhage	2	1.7
12.	Ischemic stroke	2	1.7
13.	Acute respiratory failure requiring prolonged intubation and temporary tracheostomy	2	1.7
14.	Myocardial infarction	1	0.8

B. Late

No.	Complication	No. of cases	%
1.	Empyema in the operated hemithorax	5	4.3
2.	Bronchial stump fistula	4	3.5
3.	Pleurisy	3	2.6
4.	Pulmonary embolism	2	1.7
5.	Pneumothorax	2	1.7
6.	Bronchopneumonia	1	0.8
7.	Sepsis	1	0.8

CONCLUSIONS

Our study showed a significantly higher incidence of lung cancer in various locations in men aged 40-85 years, living in urban areas, long-term active smokers, and presenting varied and multiple co morbidities. All patients received surgery, often laborious, and the incidence of early or late postoperative complications was relatively low.

VENOUS PULMONARY THROMBOEMBOLISM AND ATHEROTHROMBOSIS: NEED FOR A NEW APPROACH

Viviana Aursulesei[1], Iulia Cristina Roca[2]

2. Discipline of Emergency Medicine

VENOUS PULMONARY THROMBOEMBOLISM AND ATHEROTHROMBOSIS: NEED FOR A NEW APPROACH (Abstract): Pulmonary venous thromboembolism and atherothrombosis are traditionally considered as distinct diseases. As the two entities share common risk factors and mechanisms current experimental and clinical studies support their mutual causal relationship. For the clinician, the current concept requires a different clinical, laboratory and therapeutic approach. The patient with a first arterial or venous thrombosis should be fully assessed for the risk of future clinical events, and, simultaneously addressed to aggressive preventive non-pharmacological and pharmacotherapy intervention. In this context, antiplatelet agents and statins have a potentially beneficial role. **Keywords**: VENOUS THROMBOEMBOLISM, ATHEROTHROMBOSIS, INTEGRATED APPROACH, RISK FACTORS, PREVENTION.

CONCEPTUAL EVOLUTION

The relation between the complications of atherosclerosis (ATS) and pulmonary venous thromboembolism (VTE) is a current topic as both entities are of major importance in the prevalence and potentially fatal consequences, and according to studies, are frequently associated in the same patient. The literature of recent years supports the "VTE-atherothrombosis concept", a dynamic point of view with three stages of development (1). The classical approach supports two distinct categories of diseases based on some different types of arguments. The hemodynamic arguments refer to vascular occlusion in areas with different shear stress regimens, and pathological arguments are based on the different structure of thrombi. Venous thrombi are mainly composed of erythrocytes and fibrin, while arterial systemic thrombi are platelet-rich. Epidemiological studies also make a clear distinction between the mechanisms involved and risk factors. The distinction is also therapeutic as anticoagulation is the cornerstone of treatment in VTE while antiplatelet agents play a key role in prevention of atherothrombotic events. The classic paradigm started to be questioned at the beginning of the 21st century when epidemiological studies suggested that the dichotomy is an artificial simplification (2-5). This new stage is based on data related to a significantly increased incidence of VTE compared to the general population in the elderly and patients with a history of

peripheral arterial disease, hypertension, and dyslipidemia. The observations referring to unprovoked VTE in over 30% of the cases also support the new point of view (6). Other studies suggest common risk factors for arterial and venous thrombotic events, such as hiperhomocysteinemia, thrombophilia, or first refer to the benefit of statins in VTE (7,8). These observations recall Macfarlane's assertion in the 70s that "thrombosis is hemostasis in the wrong place" (9). In other words, the prothrombotic status secondary to platelet activation, coagulation, and increased fibrin turnover is a common event in atherothrombosis (ATT) and VTE. Based on this evidence, Prandoni examined whether asymptomatic carotid ATS is predictable for the risk of VTE (5). The study considered to be a reference for the evolution of the concept, included 299 patients with spontaneous and provoked deep vein thrombosis (DVT) and with no athero-thrombotic events, and 150 control subjects, examined by ultrasound for carotid plaques detection. The authors concluded that asymptomatic carotid lesions had significantly higher prevalence in the subgroup with provoked DVT, suggesting the potential of ATS to induce VTE. The hypothesis of an association between arterial and venous thrombotic events develops simultaneously in many prospective studies in order to elucidate the relationship direction: ATT-VTE or VTE-ATT? Data published after ‘2000s are crucial for the evolution towards the modern conceptual stage. The current paradigm argues that VTE is part of "pan-cardiovascular syndrome" that includes all clinical manifestations of ATT as there are common risk factors and mechanisms. It is concluded that between VTE and ATT there is not a simple association but a mutual causal relationship (6).

EVIDENCE FROM TRIALS

1. Atherosclerosis and risk of VTE: is there a relationship?

A first group of observations refers to the impact of subclinical ATS on the risk of VTE. There are two reference prospective population trials with the same objective as the study by Prandoni, but with conflicting results. Atherosclerotic Risk in Communities, which included asymptomatic adults aged 45-64 years, does not support the relationship. The Cardiovascular Health Study, addressed to elderly over 65 years, states low risk of VTE irrespective of etiology only related to carotid ATS but without evidence of subclinical ATS in other arterial territories (10,11). Another group of studies addresses the issue of atherothrombotic cardiovascular events (CVE). There are consistent published data but differently supporting the positive relationship with increased risk of VTE. There are interesting observations published by Eliasson et al. in a retrospective study of 23,976 consecutive autopsies in patients with objectively verified arterial and venous thrombosis. The authors suggested a heterogeneous relationship since the risk of VTE was confirmed in patients with thrombosis of the aorta and its branches, except the coronary arteries. An inadequately motivated explanation of these results is related to the ‘90s when fewer therapeutic options for acute coronary syndromes were available, and thus many patients did not survive long enough to develop VTE (12). The results are contradictory to Tromsø and HUNT-2 studies supporting that family history of acute myocardial infarction (AMI) is significantly and independently associated with the

risk of VTE (13,14). More recent data confirm the high risk of VTE during the first 3 months after AMI or stroke, then it decreases but remains statistically significant (15).

2. VTE and the risk of atherothrombosis: is there a relationship?

One of the first relevant prospective studies belongs to Prandoni showing a doubling in the risk of atherothrombotic symptomatic events following an unprovoked VTE episode compared with a secondary VTE (15.1% *versus* 8.5%), irrespective of age and other cardiovascular risk factors (16). To the contrary, Spencer stated that the relation between unprovoked VTE and AMI is age-dependent. Thus, patients younger than 40 years without atherosclerotic risk factors had a 4-fold higher incidence of AMI over 10-years of follow-up as compared to the control group (17). In addition, the study highlighted the risk of VTE recurrence within 8 years of warfarin discontinuation (30% of cases) and an about 40% increase in the subsequent risk of all-cause death (17,18). Reference data are also available from a prospective Danish trial on a cohort of more than 200,000 patients followed-up for 20 years (19). The same temporal trend was noticed when VTE was related to AMI and stroke, with an excess of relative risk for major CVE during the first year of follow-up (1.6-fold increased risk for AMI, 2.6-fold increased risk for stroke in DVT cohort, and 2.6-2.93-fold increased risk in patients with pulmonary embolism). The risk was still increased by 20-40% over the 19 years of follow-up. In a meta-analysis summarizing the literature results published until 2010, Becattini stated that patients with unprovoked VTE have a 1.5-fold higher risk of arterial CVE over 10 years than patients with provoked VTE and the general population. The meta-analysis highlights common mechanisms such as thrombogenesis, endothelial dysfunction, and inflammation. These mechanisms are supported by the modern paradigm that is focused on the causal relationship between VTE and ATT (20,21). For a clinician, these studies imply a careful monitoring of cardiovascular risk factors in patients with a history of unprovoked VTE when considering an optimal primary prevention of atherothrombotic events concomitant with recurrent venous thrombotic event prophylaxis (22).

VTE- ATHERO-THROMBOSIS CONCEPT: CLINICAL ASSOCIATION OR CAUSAL RELATION?

Abandoning classical mechanistic thinking and the need of an integrated approach of these two entities were recognized by the North American Thrombosis Summit in 2011. At this point, the relationship is reviewed in terms of pathogenesis, clinical and therapeutic management. The new concept supports VTE and ATT clinical events as a continuous spectrum of the same disease in the same patient and the risk is increased in a mutual manner.

Common risk factors and common mechanisms?

The statement that the patients with atherothrombotic events are at increased risk of VTE and *vice versa* is based on several studies that support common risk factors. Age is also a powerful risk factor in VTE, as Worcester study show an exponential increase in incidence in both sexes (23). Ageno's meta-analysis of over 65,000 patients included in 21 studies adds valuable information regarding the relation between

the major risk factors and VTE (24). Obesity expressed by body mass index doubles the risk of VTE. This observation is consistent with other studies on cohorts of women, where obesity significantly increases the risk of DVT and triples the risk of unprovoked VTE (6). Hypertension is associated with a 50% increase in the risk of VTE, a relation admitted inconstantly by other studies because of the different ways of reporting high blood pressure. Diabetes mellitus is associated with a 42% increase of VTE incidence, regardless of the trials included in the meta-analysis and type of diabetes (24). As to dyslipidemia, only decreased HDL doubles the risk of VTE and triglycerides are on average 21 mg% higher. However, smoking has a controversial influence. Ageno does not support its role, while two recent studies confirm previous results on the effect dependent on the daily number of cigarettes. Therefore, more than 25 cigarettes doubles the risk of VTE, and more than 35 cigarettes triples it (25,26). Information is extended to other risk factors for ATT. Although there are data supporting that the metabolic syndrome increases the risk of VTE by up to 84%, it is not clear whether actually it is its components, mainly abdominal obesity and non-alcoholic fatty liver, that have a major role, (6, 22). There are also controversies about the influence of age, prevalence in males, and involved mechanism. The central role of prothrombotic status activated by athero-genic mediators released by adipocytes (leptin, IL-6, TNF-α) has been stated. The VLDL trigger effect on platelet activation and PAI-1 gene expression or hyperglycemia effect on the structure and function of fibrin, generating a clot more resistant to fibrinolysis (27), is discussed. Microalbuminuria is suggested as an independent risk marker for VTE and its recurrence by the Dutch trial PREVEND. The study states a direct relationship between the amount of urinary albumin and the annual incidence of VTE (28). Hormone replacement therapy is classically linked to both a triple risk of atherothombotic events and a double risk of VTE, and Pomp's study confirms the synergistic role of smoking (1.29). Nutritional factors are supported by numerous studies. In a cohort of 14,962 patients followed-up for 12 years, daily consumption of fruits and vegetables was associated with decreased risk, whereas dietary intake of red and processed meat doubled the incidence of VTE. Eating fish at least once a week is also demonstrated to reduce the risk by 30-45% (Steffen LM cited by 6). Other prospective studies independently associate stress with increased risk of VTE in men (30). An interesting idea is suggested by Sorensen demonstrating increased risk of VTE within the first 3 months in patients with cardiovascular diseases that are potential sources of thrombi (AMI, heart failure, atrial fibrillation, especially right heart valvulopaties) in the absence of DVT (31). Finally, risk factors and clinical conditions such as hiperhomocysteinemia, thrombophilia, antiphospholipid syndrome, malignancy, chemotherapy, specific acute infections (AIDS, *Chlamydia pneumoniae*), intestinal inflammatory diseases, etc. have been linked with both arterial and venous thrombotic events (22). If the data on traditional risk factors are largely consistent, the underlying mechanisms responsible for this association are controversial. The classic triad of Virchow is still valid in VTE, but it is now believed that stasis and hypercoagulability are critical as experimentally the vascular endothelial surface is initially intact (27).

Activation and endothelial injury play a crucial role as a minor damage unprovoked by immobilization or surgery increases by 5-fold the risk of DVT (32). Based on experimental models of venous thrombosis and using electron microscopy studies, Mackman shows the role of inflammation in endothelial activation and injury, irrespective of hypoxia. It results in P-selectin, E-selectin and von Willebrand factor expression. Activated endothelial cell captures leukocytes, platelets and microparticules derived from activated monocytes. Both microparticules (membrane fragments) and neutrophils express tissue factor. It is considered that tissue factor activity is crucial for the activation of coagulation cascade and fibrin-rich, erythrocyte-rich thrombi formation (33,34). Venous wall inflammation is an early phenomenon, present in patients with uncomplicated varicose veins being induced by oxidative stress similarly to damage of the arterial wall (35). Clinical studies support the role of inflammation linking the intestinal inflammatory diseases, vasculitis or genetic polymorphisms of interleukins with the increased risk of VTE (6). For example, ARIC study demonstrates an increase by 76% of VTE risk related to C-reactive protein (36), and JUPITER trial states a 43% lower risk in patients with initially increased C-reactive protein level treated with rosuvastatin (37). Recent data also support the role of inflammation in promoting atherogenesis, destabilization of atheroma plaque, and atherothrombotic complications. The focus is on neutrophils, as there is a direct link between neutrophil count, neutrophil-related biomarkers (myeloperoxidase, elastase), and cardiovascular risk factors (38). Activated platelet-derived microparticles also seem to be involved in coronary events by inducing and stimulating massive platelet and fibrin deposition (39). All evidence supports the causal relationship between VTE and ATT, centered on the role of inflammation.

HOW THE CURRENT CONCEPT SHOULD BE APPROACHED IN PRACTICE?

In clinical practice, is fundamental to use an integrated clinical, laboratory and therapeutic approach for assessing each patient with a first arterial or venous thrombotic event. According to this concept, VTE is an early event that expresses a generalized vascular disease, present from the beginning in both types of circulation. As a result, therapeutic interventions should be similar as for a patient with severe ATS, with emphasis on active detection and optimization of risk factors. A routine screening for asymptomatic ATS following a VTE episode remains a goal of future studies (1). To the opposite, patients with atherothrombotic CVE are an underrecongnized population at risk for VTE. The analysis of the Healthcare Cost and Utilization Project Nationwide Inpatient Sample database found that more than 1 million patients with AMI and stroke develop VTE (6). Identification of VTE high risk subgroup in this large category of patients may be an additional target in its primary prevention. According to evidence from trials, major cardiovascular risk factors optimization could also be an additional way of prevention (1,6). When referring to laboratory assessment, an ambitious goal is to determine individual vulnerability inherent in venous thrombosis. Although in practice there are multiple parameters for coagulation and fibrinolysis assessment, most patients with VTE have normal tests (40). The development of sensitive tests specific to

other pathogenic pathways is a currently studied direction. Platelet membrane phospholipid, inhibition of leukocyte-released tissue factor or monocyte recruitment are some of the studied targets. Also, platelet clot volume or the particular fibrin clot phenotype characterized by a highly branched network structure with lower clot permeability and prolonged lysis time are suggested as common mechanisms linking arterial and venous thrombosis (40,41). For therapy, the major objective remains prophylaxis optimization. The multicenter, multinational trial ENDORSE points out that 51.8% of hospitalized patients have increased risk of VTE, and yet, the rate of suitable prophylaxis is reduced – 58.5% in surgical patients and 39.5% in high risk medical patients (42). Therefore, for vulnerable patients the U.S. medical system recommends implementation of computerized algorithm-based strategies, and the introduction of this issue to health policies (43). The anticoagulation benefit is extended to prophylaxis of recurrences, so as in patients with unprovoked VTE an indefinite period is recommended (6). The potential for primary prevention of AMI (reducing the incidence by 39%) is an additional reason according to a randomized trial in healthy men at high cardiovascular risk (5). A largely debated direction is the role of aspirin in primary and secondary prevention of VTE. The potentially beneficial effect is based on inhibition of platelet activation and aggregation together with interfering with acetylation of protein molecules such as fibrinogen (39). Early studies and the related APTc meta-analysis indicate a 25-30% decrease of VTE incidence in hospitalized patients at high risk treated with aspirin. The same data suggest the prevention of VTE recurrence when aspirin is given to patients at risk higher than 2% for coronary heart disease or stroke who had discontinued the oral anticoagulant therapy (44). Two recent trials with similar design support the benefit of aspirin in secondary prevention of unprovoked VTE. The WARFASA prospective study demonstrates that aspirin 100 mg/day reduces the recurrence rate by about 40% without increasing bleeding risk in patients who had completed 6 to 18 months of oral anticoagulation treatment (45). Similarly, the ASPIRE study states a 32% reduction in the rate of recurrent VTE and by 34% of major CVE without clinically relevant bleeding risk during 37.2 months of follow-up (46). However, current guidelines do not recommend antiplatelet prevention given the higher net benefit of anticoagulant therapy, including new anticoagulants. The role of antiplatelet agents for long-term prevention of VTE remains to be defined, but it is a cheap, well-known, widely available, more secure therapy, with extended benefits in the primary prevention of atherothrombotic events when anticoagulation is contraindicated. Finally, a highly debated and controversial topic is the role of statins in VTE. The potential beneficial effect is based on the antithrombotic role mediated by the decrease in platelet activation, up-regulation of thrombomodulin expression by the endothelial cells, increased susceptibility of fibrin to lysis, as well as on the anti-inflammatory role focused on reducing tissue factor, C-reactive protein, IL-6 and IL-8, MCP-1 expression (47). A secondary analysis in the JUPITER trial supports the benefit of rosuvastatin 20 mg/day in decreasing by 43% the risk of symptomatic VTE in healthy subjects. Two recent meta-analyses admit the benefit of statins in primary prevention of VTE, but at a much lower level (about 11%). The need to adjust data related to selected population, objec-

tive, associated therapy, age, statin type, etc. account for the attenuated optimistic results of previous studies (48,49). The only way to clarify the role in primary VTE prevention is to initiate a randomized prospective trial, with venous thrombosis as primary endpoint (50). Recently, information about the beneficial effect of statins has been supplemented with data on secondary prevention. Two recent Danish studies state a reduction by about 50% in the rate of recurrent VTE associated with a 30% reduction in the incidence of CVE and the relationship is dose dependent but not influenced by antivitamin K therapy. As with the primary prevention, the results need to be clarified by prospective randomized placebo-controlled trials (51, 52).

Evidence from clinical studied suggest that a new integrated approach should be applied to patients with venous or arterial thrombosis. An individualized attitude based on comprehensive assessment of total prothrombotic burden is required in order to provide a more efficient antithrombotic prevention.

SINGULAR CASE OF THIRD VENTRICLE METASTASIS OF COLORECTAL CARCINOMA CASE REPORT(Abstract): Third ventricle tumors are uncommon central nervous system lesions and unusual locations for metastatic colorectal cancer. We present a case of a 68 year old woman with a solitary 3rd ventricle lesion found on a computed tomography scan of the brain and the synchronous mass of the right colon. The aim in this case was local control of cerebral lesion with pathological diagnosis. Surgery was followed by a short term good evolution but with sudden death. **Keywords**: BRAIN METASTASES, THIRD VENTRICLE, COLORECTAL CANCER.

Metastatic brain tumors from colorectal cancer are relatively rare. The incidence ranges from 1.9 to 3.5 percent of all metastatic brain tumors (1) with a median value of 2.3 percent in the latest studies (9). Left-sided primary colon tumors were predominate and the cerebellum was the most common area of brain involvement. Tumors of the ventricular system account for less than 1% of intracranial lesions and 18.5% of them occur in the third ventricle (16). The most frequent lesions are colloid cysts (55%) and gliomas (19%), other tumors are uncommon (7). Those statistics data denote a very rare and extremely rare localization of brain metastases in the 3rd ventricle. Furthermore this location represents a challenge in terms of medical and surgical approach(12).

CASE REPORT

A 68 year old female presented with headache with a short term onset (apparently one week before admission - according to family anamnesis) associated with dizziness and mixed aphasia. She was admitted in neurology department and she had performed a contrast enhancement computed tomography (CT) scan of the brain which showed a lesion located on the 3rd ventricle topography, well defined with polycyclic aspect (fig. 1).

The laboratory studies denoted an iron deficiency anemia: Hb= 9.7g /dl; MCV=72;

MCHC= 30.6 g/dl. She was transferred in neurosurgical department and shortly after that she became comatose. A new CT scan has been performed and it revealed a hemorrhage around the 3rd ventricle lesion, in the 4th ventricle and internal active hydrocephalus predominant on the left lateral ventricle (fig. 2). We performed an external ventricular drainage (EVD) on the left side and after patient stabilization (the same day) we did a contrast enhancement brain MRI (fig. 3).

a. b. c.

Fig. 3. a, b T1WI C+ , c T2WI lobulated lesion on the topography of the 3rd ventricle with enhancement and active hydrocephalus prevalent on the left lateral ventricle.

In order to assess the origin of the anemia we performed an abdominal ultrasound examination followed by an abdominal CT scan which confirmed the presence of a tumor located on the ascending colon with a diameter of 92/53/90 mm (fig.4). Our next step was to proceed to the second stage intervention aiming to resect as much as possible from the tumor. Previously to the second intervention we removed the external ventricular drainage. We performed a precorronary transcallosal ap-

proach. The intraoperative histological examination revealed moderately differentiated adenocarcinoma.

Her postoperative course was relatively good in the first day with progressive general worsening after that. The CT scan showed the persistence of the hydrocephalus (fig 5). A new EVD was placed and the patient had a slight recovery. Unfortunately the evolution with cardiac arrhythmia and decease of the patient was registered 4 days after the tumor removal.

DISCUSSION

Brain metastases are the most common intracranial tumors in adults; the latest reports revealing that 10 - 40 % of the cancer patients will develop lesions in this specific location (14). The most common primary cancers metastasizing to the brain are lung cancer (50%), breast cancer (15%–20%), unknown primary cancer (10%–15%), melanoma (10%) and colon cancer (5%) (8, 11).

The incidence of 3rd ventricle lesions is very low (4). We haven't found yet cases of 3rd ventricle colorectal metastasis mentioned in literature. As far as we know it was a singular case. Colorectal cancer usually metastasize in the liver or in the lung, very rarely as primary brain metastasis. In our case the histopathological result revealed moderately differentiated adenocarcinoma with epithelial tumoral cells showing cytological features of neoplasia. It presented areas of papillary fronds arranged around a fibro-vascular core (Fig. 6a) and expressing epithelial anaplasic cells arranged as irregular gland-like structures in a back-to-back fashion. (fig. 6b) In the light of the results of the abdominal examination the probability for a metastatic tumor of gastrointestinal origin is very high and according to some studies the median survival after surgery for gastrointestinal brain metatstasis is 9.1 months (1) while after radiosurgery is 6.7 months (2), so the surgery may be more beneficial than other oncologic therapies in this specific case.

The patient was diagnosed with anemia previously to the intervention but the swift neurological deterioration allowed us to find the cause of anemia after EVD.

a.  b. 
Fig. 6. a. Tumoral cells form papillary fronds b. expressing epithelial anaplasic cells arranged as irregular gland-like structures

From the beginning the synchronized diagnosis of a brain metastasis and colorectal cancer indicates a late stage gastrointestinal tumor and consecutively a poor prognosis (3). The latest data found that gastrointestinal tract tumors (already metastasized in the brain) were associated with a shorter median survival than even melanoma (6).

The patient presented with acute obstructive hydrocephalus due to both - tumor extension per se and intraventricular bleeding, imposed EVD and surgical intervention with the aim of ventricle repermeabilisation by tumor debulking and histopathological confirmation.

Technical considerations. We have chosen a transcallosal approach on the left side (5, 13). We did an "S" shaped incision starting from the left side, from the incision for the EVD with a parasagittal craniotomy centered on the former burr hole for EVD. We distinguished the superior sagittal sinus which presented a voluminous venous dilatation without any important drainage. Parasagittal dissection of adherences between the 2 hemispheres was followed by a 2 cm long callosotomy with ultrasound aspirator and entrance in the ventricular system and evacuation of the CSF under pressure. The choroid plexus was visualized and the inferior one quarter of the septum seemed infiltrated, the fornix was pushed upward and the cleavage plane was difficult to find. We resected the tumor with the aid of ultrasonic aspirator until we saw the lateral wall of the third ventricle. The tumor was well vascularised, adherent to the choroid plexus and veins while in the center it had a grey, fatty aspect.

We considered it was too dangerous to continue debulking because of the absence of the cleavage plane, the presence of the adherences to the wall of the ventricle and difficulties in visualization of the bleeding sources. We have chosen the classic intervention and not the stereotactic biopsy because of the presence of obstructive hydrocephalus and we didn't chose also the endoscopic approach (10,15) because of the likelihood of bleeding and poor control of hemostasis. Intra operative there were no major complication but the resection was stopped because of the lack of the differention in between the tumor mass and the diencephalic structures.

The initial evolution after surgery was good with no more deficits. The unfortunate evolution with cardiac arrhythmia and death

was registered. The patient did not suffer of another new hemorrhage or recent ischemia, on the control CT scan and she presented no hydroelectrolytic disturbances. She also didn't respond to the replacement of EVD. Sudden death is cited in lesions that are infiltrating the diencephalon.

CONCLUSIONS

The 3rd ventricle metastases are unusual lesions with difficult evolution and with poor prognosis especially when they are diagnosed synchronically with a primary intestinal lesion and they may be complicated with sudden death.

SMOKING GENERATED $PM_{2.5}$ EXPOSURE AMONG TRANSYLVANIAN STUDENTS (Abstract)**:** A WHO project initiated in 2004, tries to identify and reduce the number of smoking third year university students attending medical training in Medicine, Dentistry, Pharmaceutical sciences as these participants can become role models that patients can look up to. **Aim**: we proposed to make a general view regarding smoking and exposure to smoke within our medical University, in contrast with the existing legislation regarding smoking within public institutions of the Universities. Along with the investigations held at our university we extended these to other tree, non medical universities. **Materials and methods:** using an TSI Pack Aerosol Monitor unit to measure the total PM $_{2.5}$ we determined the air quality in several target locations of our University in holiday season and during full didactical periods. The average values were later compared and assessed in a series of statistical tests. **Results:** analyzing the holiday period our university head the most polluted air showing the P.M. 2.5 of 0.016 mg/m^3. In the following there were analyzed the recordings from the didactic period where the registered values were significantly higher ($p<0.0001$) in comparison with the readings from the holiday season. From several points within the universities there were reading 7 times higher than in the holiday season. **Conclusions:** the results show two evident conclusion, that there is smoking within the buildings of the universities and within our university the non-smoking students are totally exposed to exhaled cigarette smoke. **Keywords:** SMOKING, STUDENT, PM $_{2.5}$, SECOND HAND SMOKING EXPOSURE.

According to WHO estimates, about 6 million people die annually due to smoking, of which about 5.5 million smokers, and the remaining 500.000 people due to passive smoking. WHO initiated a study in 2004 (called Global Health Professions Student Survey), which reached until 2010 approximately 50 countries and focused on identifying smokers and reducing smoking among students of medical universities (medicine, pharmacy, dentistry, nursing, etc.) starting from their 3rd year of studies, considering that as they will become doctors, dentists, pharmacists, they will be considered role models by thousands of patients. Romania joined this study in 2010 (1).

Another recent study performed in Romania identified smoking as an important issue among young adults aged over 19 years. This even called tobacco smoking a

lifestyle component of young people in Romania, its incidence increasing by 15% from the age group of 14-18 years to the age group of over 19 years (2).

Among the toxic emissions of smoking there are several substances, some of which are known carcinogens. Additionally, cigarette combustion products are known to be small, suspended particles, especially those under 2.5 μm (fine particle - PM $_{2.5}$) that penetrate as deep as the alveoli. A significant association between these particles and premature mortality has been reported in several studies. Worsening of chronic cardiovascular and respiratory diseases have been reviewed, as well as the occurrence of impaired lung function and airway irritation syndrome, with symptoms such as cough, shortness of breath, wheezing in otherwise healthy children and adults. This is why exposure to passive smoking - second hand smoking receives a special importance in the etiology of many diseases, not only among smokers, but also among non-smokers (3).

In support of non-smokers from all over Europe come a series of laws that prohibit smoking in somewhat restricted or more extensive areas. According to 2013 WHO reports, smoking prevalence in Romania is 25% and it is proving to be a European country to make some efforts in the adoption of laws to protect its citizens, both non-smokers and smokers (4).

Nevertheless, legislation in force still allows smoking in bars, restaurants, discos, and in public places, even in public institutions, in specially designated areas (5). This means that the Romanian citizen could be protected to some extent by legislation from exposure to cigarette smoke.

Since the strengthening of the smoking habit occurs somewhere around 18-19 years of age, and because students from medical universities may be key figures for future patients, we focused on this population, establishing certain key questions (research question).

The study evaluates compliance with the regulations against smoking in universities in Romania that aim to protect non-smoking students and employees. It will answer the question whether the University of Medicine and Pharmacy complies with the above mentioned legislation more or less than other, non-medical universities?

MATERIAL AND METHODS

Measurements of PM $_{2.5}$ particle concentrations were performed with an AM510 TSI Pack Aerosol Monitor device (6, 7). Recordings of PM $_{2.5}$ values came from central buildings of four universities. These buildings were previously evaluated, and potentially contaminated sites were identified (4-5 for each). Then, for each of the four to five predefined sites, monitoring was performed for 10-14 minutes by recording data every second. This has been done first during the holidays (minimum, constant employee activity), thus obtaining a baseline data for the following: site A - 3521 data from the central building of a state held medical university (medicine, pharmacy, dentistry, nursing) in Transylvania; site B- 3426 data from a state held university with non-medical profile, site C - 3045 data from a private university, site D - 3483 data from another private university with environmental profile. The averages of the PM $_{2.5}$ measurement values of the four universities were compared. Data were processed using Microsoft Office Excel.

The next step was to carry out measurements at site A (medical university) during full teaching activities, between

Tuesday and Thursday, from 10 to 12 and 14 to 16 hours, maintaining the sites of measurement. Recording was performed every 30th second. The evolution of the $PM_{2.5}$ particles from the first to the second measurement was noted and compared using statistical tests for nonparametric, unpaired data (Mann Whitney U) using the Graph Pad Instat software.

In case of the A university, the evolution of values from the teaching period compared to the holidays was also analyzed for each measurement site.

RESULTS

In the first phase, a pre-screening of the central buildings of the four universities has been performed, in order to establish potentially contaminated sites. Following establishment of these sites, the aerosol monitor has been deployed. The results of concentration measurements of fine particles during holidays placed site A (Transylvanian medical university) first. The 3521 measurements performed at five different areas, with a total measurement time of 58 minutes and 41 seconds averaged a value of 0.0168 mg/m^3. Second place, very close to the first, was taken by the non-medical state held university (site B). Its 3426 measurements collected from five different points in 57 minutes and 6 seconds, resulted an average of 0.0153 mg/m^3. In case of the private university – site C – the average value was 0.0140 mg/m^3 from 3045 measurements performed in four areas, and a total measurement time of 50 minutes and 45 seconds.

The lowest concentration was found at site D, (private university with environmental profile), where an average of 0.0059 mg/m^3 was calculated from 3483 measurements collected from five different points in 58 minutes and 7 seconds. All measurements from all areas were recorded every second (tab. I).

TABLE I

Average $PM_{2.5}$ measurements of the four universities in Transylvania

No.	University	Meas. No.	Meas. time	Average mg/m^3
1.	A –state held medical	3521	58:41	0.0168
2.	B –state held non-medical	3426	57:06	0.0153
3.	C – privately held	3045	50:45	0.0140
4.	D –privately held ecological	3483	58:07	0.0059

Next we went on to monitor the teaching period of university A. In order to obtain the most relevant results, we focused on maximum activity intervals during the week (Tuesday, Wednesday and Thursday), between 10 and 12, and 14 and 16 hours. The second set of measurements was not taken in the same place on the same day. Results obtained in the interval between 10 and 12 were compared for each measurement area with those recorded between 14 and 16 hours on another day (tab. II).

E- stair case 1st-2nd level, administrative zones neighborhood, next to a coffee machine; F- men's restroom, 1st floor; G- women's restroom, 1st floor; H- ground

floor corridor, doorman rooms neighbor- hood

TABLE II

Comparison of PM $_{2.5}$ value medians of the measurement areas

No.	Meas. area	Meas. No. 10-12/14-16	Median 10-12 h mg/m^3	Median 14-16 h mg/m^3	Mann W.U. test
1.	E	246/238	0.0258	0.0513	p<0.0001
2.	F	240/240	0.01051	0.01058	p=0.413
3.	G	237/240	0.0105	0.0124	p<0.001
4.	H	237/238	0.0258	0.0513	p<0.0001

Significant increase	No significant result	Significant decrease

So we see that in two of the above areas (E and G) the values increase significantly, there is no change (F) in one area and in one area (the one next to the doorman's room) (area H) there is a decrease during the second interval.

The next step was to compare the values obtained during the holidays with those obtained during full teaching activities for each of the measurement areas. For the teaching period, we used the values of both of recorded time intervals from one measurement area. The results show a significant increase in all recorded parameters at each measurement area; in one area there is even a 7-fold increase compared to the holiday period (tab. III).

DISCUSSION

Although in 2010 Romania joined the project initiated by the WHO - Global Health Professions Student Survey (GHPSS) – its results, the country report cannot be found between the reports from the other participating countries. This would provide information about smoking habits of students of the medical university, and about their desire to stop this habit. In their knowledge effective prevention programs could be developed. This is why the value of this study is important, because it shows objectively the presence of PM $_{2.5}$ particles from tobacco smoke inside the main building of the evaluated university (A) (1).

TABLE III

Comparison of PM $_{2.5}$ value medians of the holiday period and teaching period

No.	Meas. points	Meas. No. Hol./Tea.	Holiday median (mg/ m^3)	Teaching period median (mg/ m^3)	Mann W.U. test
1.	E	801/484	0.0127	0.0383	p<0.0001
2.	F	686/480	0.00934	0.0105	p<0.001
3.	G	686/477		0.0115	p<0.001
4.	H	612/475	0.0087	0.0567	p<0.0001

E- stair case 1st-2nd floor, administrative zones neighborhood, next to a coffee machine; F- men's restroom, 1st floor; G- women's restroom, 1st floor; H- ground floor corridor, doorman rooms neighborhood

very significant-7x

Moreover, comparing the values measured at different universities, it emerged that the medical university (A) has the most polluted air in the holiday period, which incriminates the administrative and ancillary staff. Private universities have complied more rigorously with regulations (5) concerning smoking prohibition in public buildings and institutions (C and D), but it should not be neglected that these are equipped with smoke alarms. But the law is broken not only in Romania: a study using the same methodology and measurements, performed at certain hospitals in Hungary to measure $PM_{2.5}$ with a TSI Aerosol Monitor Pack, showed that employees are smoking in their premises, even if it is strictly forbidden (8). A recent study in Romania, speaks of the smoking habit of young adults as a "lifestyle component" (2). Our study demonstrates as well that besides employees, students also greatly contribute to increased values of $PM_{2.5}$. This is demonstrated both by the significant increase in two of the measurement areas (E and G) of the medians of the 10-12 and 14-16 intervals, and by the comparison of values recorded during the teaching period to the values of the holiday period, which were statistically significantly higher when students were present. Therefore a program encouraging smoking cessation, as well as enforcement of existing legislation would be welcome.

Lastly, the not so very good position of Transylvanian universities regarding clean air is suggested by a study conducted in 32 countries in 2008; the study measured and analyzed the $PM_{2.5}$ values in a total of 1822 bars and restaurants, among others, in also Romania. Unfortunately, our country was in second place regarding air pollution by $PM_{2.5}$. It is to be noted the air quality in New Zealand regarding $PM_{2.5}$ contents. The restaurants in this country have cleaner air than some of our universities (0.008 mg/m^3, as compared to 0.0168 mg/m^3 at university A, 0.0153 mg/m^3 at university B and 0.0140 mg/m^3 at university C) (9).

CONCLUSIONS

This study may add to the WHO project initiated in Romania in 2010, proving objectively the presence of smoking within the Medical University. It turned out that both employees (based on the results of the holiday period), and students (based on the results of the teaching period) smoked at the premises of the Medical University. This also reveals the importance of informing the smoker, as well as the non-smoker students to promote cessation of active smoking, and avoid secondhand smoke, and in order to develop prevention programs and effective interventions.

Legal regulations regarding smoking in public institutions are often violated by university students, and staff both at the medical university, as well as other universities. A smoke alarm system may help law enforcement, thus preventing student-employee exposure to second hand smoke. The method of measuring fine particles can be used to test a future intervention among students.

ACKNOWLEDGEMENTS: The study was supported by the Fogarty Foundation NGO in collaboration with the Davidson Medical College North Carolina and the Medical School of Semmelweis University Budapest, and it is part of an international grant “Building Capacity for Tobacco Research in Romania”. Thank you goes out to the managements of the universities for allowing the recording of the presented data.

MATHEMATICAL MODEL EXPLAINS BACTERIA- HOST INTERACTIONS IN LYME DISEASE

The Lyme disease is a borreliosis characterized in early stage, by a rash on the skin named erythema migrans, caused by the interactions between bacteria and the host immune response. In this early stage the antibiotic treatment is most effective. The cutaneous rash has three separate morphologies: homogenous erythemas, central clearing rash with a peripheral ring erythematosus and characteristic central erythemas with a bull's-eye appearance. When the aspect of rush it's not characteristic, the diagnosis is difficult. Using a mathematical model that explains bacteria- host immune response interactions, researchers Vig and Wolgemuth show that the morphology of rash and the time during spreading are linked with the rates of bacterial replication and macrophage clearing. Also, this model revealed that the antibiotic treatment clears spirochetes from the dermis in the first week for all type of erythemas, but evolution of rush morphology is not an indicator of the efficacy of the therapy.The researchers suggest that the mathematical model could be able to explains bacteria- host interactions in other bacterial infection and could be used to develop guided treatment for Lyme disease (Vig DK, Wolgemuth CW. Spatiotemporal evolution of erythema migrans, the hallmark rash of lyme disease. *Biophys J*. 2014; 106(3):763-8).

ESTIMATION OF OCHRATOXIN A IN THE HUMAN BLOOD OF ROMANIAN POPULATION (Abstract): Ochratoxin A (OTA) is a toxic secondary metabolite of fungi belonging to the *Aspergillus* and *Penicillium* genera, its presence in human blood being the primary indicator of exposure. **Aim:** In the present study we determined OTA in 38 blood samples collected from healthy Romanian subjects of both genders. **Material and methods:** The OTA was determined through the direct, competitive, solid-phase immunoenzymatic method; the minimum quantification limit for determining OTA in serum samples was 0.0289 ng/mL. **Results:** The positive sample percentage was 100%. OTA concentrations varied between < 0.04 ng/mL and 1 ng/mL. There were no significant differences between OTA concentrations in men versus women (0.24 ± 0.20 ng/mL versus 0.17 ± 0.15 ng/mL, p=0.3527). **Conclusions:** The analyzed blood samples exhibit a very high degree of exposure to OTA, but in only approximately 10% of the subjects exceeded 0.5 ng/mL, considered the threshold for OTA-induced renal pathology. **Keywords:** OCHRATOXIN A, BLOOD SAMPLES, IMMUNOENZYMATIC METHOD

Ochratoxins (A, B, C) are a group of compounds with related chemical structure, a isocoumarin derivate being linked to L-b-phenylalanine by an amide bond.

OTA is a hepatotoxic, nephrotoxic, carcinogenic, teratogenic, immunotoxic and neurotoxic compound that contaminates foods before harvesting or, more frequently, during storage (1). The mycotoxin is naturally produced by *Penicillium verrucosum* in temperate areas and by *Aspergillus ochraceus* and, more rarely, by *Aspergillus carbonarius* in tropical regions. The toxicity of OTA results from the inhibition of protein synthesis, disruption of calcium homeostasis, increased lipid peroxidation, mitochondrial dysfunction, and also through the effects at the level of transcription and transduction (2).

The purpose of this paper is to determine OTA in blood samples collected from Romanian healthy volunteers through a

solid-phase direct, competitive immunoenzymatic method.

MATERIAL AND METHODS

Reagents and equipment. STAT FAX 303 Plus ELISA microplate readers, (Awareness Technology, USA).

All reagents were multianalyte, supplied in a compact kit:

1. Calibrators with OTA in the concentration range 0.0 – 0.40 ng/mL: each kit contains multianalyte calibrators with values attributed through a reference method that attests that the values of the analytes were established according to reference materials certified by WHO for 6 levels of concentration (0.0, 0.02, 0.05, 0.1, 0.2, 0.4 ng/mL), in liquid conditioning form, that can be used as such.

2. Reagent kit for the quantitative determination of OTA, code DE991OCH01MS (Demeditec Diagnostics GmbH, Germany) containing all components for the ELISA reaction necessary for the determination of OTA.

Analyzed samples. Blood samples were collected from 38 healthy volunteers from Iasi, Romania. This study was approved by the Ethics Committee of the "Grigore T. Popa" University of Medicine and Pharmacy and was carried out in accordance with standard operation procedures. Written informed consent was obtained from all subjects before initiation of the study.

Method. The quantitative determination of OTA in human serum samples was realized through a solid-phase, direct, competitive immunoenzymatic method. The standards (calibrators) or samples are added to the polystyrene microwells coated with high-affinity antibodies and, if present, OTA couples with the antibodies. Next, OTA conjugated to the enzyme horseradish peroxidase (HRP) is added, forming bonds with the antibodies that have not yet been occupied by the OTA from the standard or sample. After a reaction incubation interval, the content is removed, the microwells are washed, and the chromogenic (3,3',5,5'-tetramethylbenzidine) (TMB) substrate is added. TMB soluble substrates yield a blue color when detecting HRP. The intensity of the color is directly proportional with the quantity of conjugate and inversely proportional with the quantity of OTA present in the standard or in the sample. The reaction is stopped by adding an acid solution that changes the color from blue to yellow. The intensity of the color is spectrophotometrically determined at 450 nm with a 630 nm reference filter.

The above described method for OTA analysis was linear for the concentration range 0.0-0.5 ng/mL, with the regression coefficient (R) = 0.968058367. The minimum detection limit was 0.0133ng/mL and the minimum quantification limit for OTA determination in serum samples was 0.0289 ng/mL.

Sample preparation. To determine OTA in human blood, the blood is collected in vacutainer serum tubes; the blood is centrifuged, the serum is separated and exposed to ethanol extraction: 750 µl absolute methanol is added to 250 µl serum. The mixture is homogenized, left at room temperature, centrifuged at 3500 rpm for 5 minutes and only the supernatant is used for OTA determination.

Procedure. The successive work steps to determine OTA in blood samples are described in tab. I.

Statistical analysis. The statistical analysis was performed using one-way analysis of variance (ANOVA) and Pearson's r. Tukey test was used for multiple comparisons (software *Stats Direct* version 2.6). A value of $p < 0.05$ was considered significant.

	Optical density was read at $\lambda = 450$ nm with 630 nm reference filter.							

RESULTS

The study population comprised 9 males (23.68%) and 29 females (76.32%) with an average age of 38.63 ± 13.08 years, 38.24 ± 13.61 for women and 39.88 ± 11.87 for men.

The majority of the study population (28 subjects) was living in urban areas (74.69%) whereas 10 patients (26.31%) were from rural areas. All study participants were white Caucasians and had a average Body Mass Index (BMI) of 22.98 ± 1.83 kg/m^2 for women and 23.36 ± 1.96 kg/m^2 for men, with no statistical difference between sexes.

All 38 plasma samples exhibited the presence of OTA in concentrations ranging between 0.04 ng/mL and 1 ng/mL. The average OTA concentration in the examined plasma samples was 0.22 ± 0.19 ng/mL. Seven subjects (18.42%) exhibited OTA concentrations less than 0.1 ng/mL, 27 subjects (71.05%) between 0.1 - 0.49 ng/mL, 3 subjects (7.89%) between 0.5 - 0.99 ng/mL, and 1 subject (2.63%) of 1 ng/mL (fig. 1). There were no significant differences in OTA concentrations between men and women (0.24 ± 0.20 ng/mL versus 0.17 ± 0.15 ng/mL, p=0.3527). Our results indicated no correlations between OTA concentrations and age or BMI.

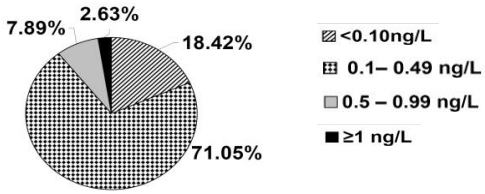

Fig. 1. The distribution of OTA concentration in blood samples from healthy Romanian subjects

DISCUSSION

OTA can be present as a natural contaminant of food and, as a consequence, it can be traced in human blood, breast milk and

animal-based products. In European diet, cereals (barley, wheat, corn and oat) and their derivatives are viewed as the major source of OTA ingestion, representing approximately 50% of the total input (1).

The importance of determining OTA plasma concentrations is related to the fact that OTA levels higher than 0.5 ng/mL are linked to the development of renal diseases (3).

The nephrotoxic action of OTA in humans was demonstrated by the occurrence of Balkan endemic nephropathy (BEN) and is associated with renal and urethral carcinoma, and, less frequently, with carcinoma of the bladder (1, 4).

Still, there are insufficient epidemiological and clinical data to demonstrate the carcinogenic potential of OTA in humans and it is considered that other nephrotoxic agents like aristolohic acid could be involved in BEN (5).

Similar studies using a detection limit of 0.025 ng/mL identified OTA in 324 of the 341 analyzed blood samples. 62% of the samples contained OTA concentrations lower than 0.2 ng/mL, while 17 samples (5.2%) presented concentrations higher than 0.50 ng/mL, indicating a low exposure of Italian population (6).

European studies reported high percentages (97%) of OTA positive blood samples at comparable detection limits, data that are in agreement with our results (7, 8). In similar studies conducted in African or Near East countries, these percentages were lower; thus, in Morocco, using a detection limit of 0.08 ng/mL the percentage of positive samples was 60%, while in Lebanon, using a detection limit of 0.60 ng/mL the percentage dropped to 33% (9, 10).

As to the difference in plasma OTA concentrations between men and women, the results are heterogeneous. Several authors indicated that plasma OTA concentration is higher in men than in women, whereas other studies revealed no significant differences between sexes (11, 12). Giuseppe et al. (2012) signaled a significant age-sensitive difference between these values in men and women, differences that were not found in our study (6).

CONCLUSIONS

In conclusion, our results indicate an increased level of exposure to OTA (100% of the blood samples), but only approximately 10% of the subjects exceeded 0.5 ng/mL considered the threshold for OTA-induced renal pathology.

ANEMIA- RISK OF DEMENTIA IN THE ELDERLY

According WHO criteria's, anemia is defined by a level of hemoglobin concentration less than 13 g/dL for men and 12 g/dL for women. This illness affects a quarter of adults over the age of 65. Another condition common in the elderly pathology is dementia. A study published in online issue of *Neurology*®, the medical journal of the American Academy of Neurology, show that anemia is associated with increased risk of dementia. The study group which includes 2552 elderly adults was investigated for anemia and cognitive disorders and memory for 11 years period. At baseline, 393 participants had anemia. At the end of the study, 23% of the patients with anemia have associated dementia. Only 17% of people without anemia have developed dementia. The increased risk of developing dementia for older adults with anemia has remained significant after adjusting for age, race, sex and education. These results suggest that anemia is a target for preventing cognitive disorders (Hong CH, Falvey C, Harris TB et al. Anemia and risk of dementia in older adults. Findings from the Health ABC study. *Neurology*, 2013 DOI: 10.1212/WNL.0b013e31829e701d).

EPIDEMIOLOGICAL ASPECTS OF HYDATIDOSIS IN CHILDREN IN SOME AREAS OF NORTH- EASTERN ROMANIA (Abstract). Hydatid cyst is a major public health problem in the pediatric population, both in terms of its frequency and of its endemic character in certain regions. **The aim** of the study was to present the incidence of hydatidosis in children who were hospitalized in pediatric clinics specialized in surgery of the Emergency Hospital for Children "St. Maria" from Iasi. **Material and methods:** Prospective study conducted in the interval 2008-2012 in a series of 194 children patients from Moldova, Romania. **Results:** The peak incidence of the hydatid disease is located around the age of 11-14 years (33%) in male patients (55%) from rural areas (79%) and families with low socioeconomic level. The hepatic localization of the hydatid cyst (50.51%) among children was more common than pulmonary localization (16.49%). Liver and lung localization was found in 22.16% of cases. **Conclusions:** Hydatidosis remains a major health problem requiring drastic measures to limit the spread and transmission of the parasite in humans, primarily by reducing the number of stray dogs. **Keywords**: *ECHINOCOCCUS GRANULOSUS*, HYDATIDOSIS, HYDATID CYST, CHILDREN.

Echinococcosis/hydatidosis are parasitic diseases in humans caused by *Echinococcus granulosus larvae* (1, 2). In the form of cysts, localized mainly in the liver, lung and not infrequently other organs, through the private development and its complications the parasite becomes the cause of various clinical and sometimes quite severe manifestations, which have turned this parasitosis into an important chapter of human pathology. Dog's role in the spread of this disease is well established (3), and from this point of view, Romania has its future assured, creating a huge reservoir of parasites, due to the large number of stray dogs (1).

The disease in humans and animals is produced by the larval form of cestode *Echinococcus granulosus* which as an adult parasitizes the small intestine of carnivores. The hydatid infection rate in our country among human and animal populations in recent years is downright alarming and is mainly due to lack of health education (4).

Hydatid disease is transmitted gastrointesinally through food infected with *Tae-*

nia echinococcus eggs (5). The main location of the hydatid cyst is the liver in a proportion of 50-60%, the second location being the one represented by the lung in a percentage of 30-40% (6).

MATERIAL AND METHODS

The study is retrospective and included a group of 194 patients, 107 males and 87 females, aged 1-18 years, hospitalized in pediatric clinics specialized in surgery of the Emergency Hospital for Children "St. Maria" from Iasi between the years 2008-2012 and diagnosed with hydatidosis. The aim of the study was to present the incidence of hydatidosis in children. Studying the admissions of the clinic, which generally concentrates the specific pathology from Moldova, we managed to constitute a statistically representative sample.

The study database was performed using the data obtained from clinical observation sheets of selected patients, paraclinical lab results and records of paraclinical and ultrasound investigations results and protocols related to surgery performed. Data from patients' medical observation sheets were entered into a Microsoft Excel spreadsheet.

RESULTS

The current study was conducted on a sample size of 194 patients diagnosed with hydatid cyst. Distribution on backgrounds (area of origin) showed differences in favor of rural areas. There is a higher proportion of patients from rural areas, a total of 154 children (79%) as compared to those in urban areas, 40 children (21%).

Distribution by sex of the value of prevalence recorded in our study shows a predominance of male versus female. Of the 194 patients, 107 were males (55%) and a total of 87 patients (45%) were females.

Fig. 1. Distribution of cases by area of origin

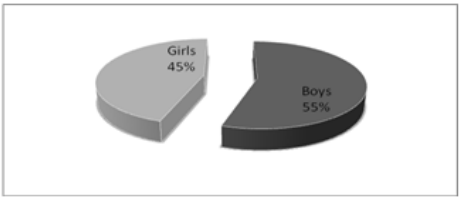

Fig. 2. The distribution of cases by sex

Regarding the distribution by age group, the hydatid cyst is found in children of different ages, showing an increased incidence in children of 11-14 years (33%) and 7-10 years (31%). The incidence is lower in toddlers and preschoolers (4%). The highest rate of hydatid cyst occurred in children with ages between 7-9 years, 11-13 years and 16-17 years.

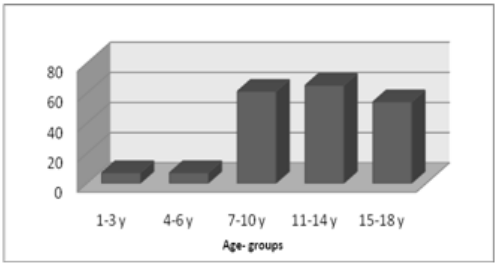

Fig. 3. Distribution of cases by age group

The possible source of infestation was the contact with the animal (dog) and the non-observance of the rules of hygiene.

Domestic animals were present in the household of patients studied, a situation which is significantly associated with an increased risk of parasites. Domestic animals are intermediate or final hosts for a large number of parasites including *Echinococcus granulosus*, the dog transporting parasite eggs on its fur (2).

The diagnosis was set through abdominal ultrasound, pulmonary X-rays and the parasitic etiology of these cystic formations was confirmed by the presence of anti-*Echinococcus granulosus* antibodies in the patient's blood.

The location of hydatid cysts was as follows: hepatic in 98 patients (50.51%), pulmonary in 32 children (16.49%), hepatic and pulmonary in 43 cases (22.16%). The number of cysts was variable: 131 children had one cyst (79.87%), 63 children (38.41%) had more than one cyst, of which 7 (4.26%) had localizations in several organs (liver, lung, spleen). Double and multiple localizations are relatively quite common and can lead to serious complications. Treatment of hydatidosis was extremely difficult, 34 patients needed surgical treatment, mainly cystectomy and for 88 children antiparasitic chemotherapy was the only method of treatment.

After surgery the disease may relapse in many cases. Given that relapses may occur after a few years these patients must be followed through imaging and immunological examinations (7).

DISCUSSION AND CONCLUSIONS

The peak incidence of hydatid disease is located around the age of 11-14 years in male patients, from rural areas coming from families with low socioeconomic level. The rural origin of most patients supports the inclusion of the disease in zoonoses (18), these patients being more exposed to a contact with pets. Hepatic location of hydatid cyst in children was more common than pulmonary location, a situation reported in other studies as well (9, 10).

Hydatid cyst is a major public health problem in the pediatric population, both in terms of frequency and of its endemic character in certain regions (11). In recent years there has been an increased incidence which proves that sanitary hygiene compliance is not rigorous, and an increase in the number of stray dogs (12).

Hydatid cyst, a parasitic disease with ubiquitous geographic distribution, far from being eradicated in our country requires a simple treatment method, with satisfactory results for both doctor and patient, both from a clinical evolutionary point of view and socio-economically.

NOSOCOMIAL INFECTIONS IN A SURGICAL INTENSIVE CARE UNIT

Medical and surgical intensive care unit patients represent two different populations and require different treatment approaches. The aim of this study was to investigate the parameters associated with mortality in medical and surgical intensive care units. A prospective cohort study of adult patients admitted to a medical and surgical intensive care unit teaching hospital over an 11-month period was performed. Factors associated with mortality were explored using logistic regression analysis. In total, 827 admissions were observed, and 525 patients >18 years old and with a length of stay >24 h were analyzed. Of these patients, 227 were in the medical and 298 were in the surgical intensive care unit. The surgical patients were older ($p<0.01$) and had shorter lengths of stay ($p<0.01$). The mortality in the intensive care unit (35.1 vs. 26.2, $p = 0.02$) and hospital (48.8 vs. 35.5, $p<0.01$) was higher for medical patients. For patients in the surgical intensive care unit, death was independently associated with the need for mechanical ventilation, prognostic score (SAPS II), community-acquired infection, nosocomial infection, and intensive care unit-acquired infection. For patients in the medical intensive care unit, death was independently associated with the need for mechanical ventilation and prognostic score. Authors concluded that, although the presence of infection is associated with a high mortality in both the medical and surgical intensive care units, the results of this prospective study suggest that infection has a greater impact in patients admitted to the surgical intensive care unit. Measures and trials to prevent and treat sepsis may be most effective in the surgical intensive care unit population. (Toufen C Junior, Franca SA, Okamoto VN, et al. Infection as an independent risk factor for mortality in the surgical intensive care unit. *Clinics (Sao Paulo)*. 2013;68(8):1103-1108.)

PRENATAL DIAGNOSIS OF GONOSOMAL ANOMALIES: LIMITATIONS OF THE FISH METHOD AND GENETIC COUNSELING DIFFICULTIES IN 15 CASES (Abstract): Prenatal diagnosis (PD) by FISH or cell culture is today an important tool for the prevention of chromosomal anomalies. A difficult issue is prenatal detection of gonosomal anomalies. Most gonosomal anomalies neither affect life expectancy nor cause psychomotor retardation, but sexualization disorders and the lack of reproductive potential are a constant finding. **Aim:** This study aimed at identifying the medical problems the specialists and the parental couple are faced with at the time of the diagnosis of fetal gonosomal anomalies. **Material and methods:** This retrospective study (2004-2012) was conducted in the Prenatal Genetic Diagnosis Department of "CuzaVoda" Maternity by FISH technique in 1685 pregnancies. The AneuVysion probes were used for identifying and enumerating chromosomes 13, 18, 21, X, and Y via fluorescence in situ hybridization (FISH) in interphase nuclei obtained from amniotic fluid. **Results:** Fifteen fetuses were selected in which we were faced with difficulties interpreting the number of gonosomes: monosomy X (5 cases), pseudomosaicism XX/XY (3), trisomy XXY (3 cases), trisomy XYY (1 case), 45,X/46,XX mosaicism (1 case) and triploidy XXX (2 cases). Later, by repeating the analysis, 2 cases with pseudomosaicism XX/XY were excluded. A case highlighting the limitations of the FISH test was that of a fetus in which the FISH test revealed trisomy XXY, while postnatal karyotyping showed a six cell line mosaicism (marker and ring X chromosomes). **Conclusions:** All parental couples received nondirective genetic counseling, respecting the individuals' dignity and rights of self-determination. Parents received information on the natural course of the disease, treatment options, and psychological support and were involved in their child's recovery.
Keywords: PRENATAL DIAGNOSIS, FISH, MONOSOMY X, TRISOMY XXY, TRISOMY XYY.

Chromosomal diseases, with an incidence of approximately 1% newborns, high severity, chronic and disabling course, can be prevented by prenatal cytogenetic diag-

nosis. It uses minimally invasive, expensive, laborious techniques of embryonic or fetal cells study, requiring a rigorous selection of cases. The indications for the prenatal diagnosis of chromosomal abnormalities are: visceral anomalies at ultrasound examination, advanced maternal age, positive biochemical screening (abnormal double or triple test), family history of chromosomal disease, and a balanced structural chromosomal abnormality in a parent (1). Fetal cells are obtained by chorionic villi biopsy, amniocentesis or cordocentesis. Classical prenatal chromosome analysis requires *in vitro* culture of fetal cells with a waiting period of 2-3 weeks. An alternative method is the fluorescent in situ hybridization (FISH), based on the hydrogen bonds formed between the DNA of the analyzed chromosome (target DNA) and fluorescently labeled DNA probe (2). Sex chromosome abnormalities are common genetic diseases, affecting 1/400 - 1/500 live births. Increased frequency is correlated with minimal phenotypic changes. Gonosomal abnormalities detected by prenatal diagnosis create difficulties in genetic counseling related to the impossibility of estimating the severity of clinical features, with the decision-making process becoming a complex medical act (3). Prenatal medicine has brought great benefits related to the reproductive choice knowing the particular circumstances, but also generated ethical controversies. Prenatal diagnosis of chromosomal disease puts the prospective parents in a position to choose between recognizing the severity of the genetic disease, understanding and accepting the chronic illness without a pathogenic treatment, or terminating the pregnancy by therapeutic abortion. Severe chromosomal disease (trisomy 13, trisomy 18 or triploidy) is not marked by these dilemmas, because keeping the pregnancy is not put into question. Instead, gonosomal anomalies allow in most cases a fairly normal life. Thus, for the gonosomal anomalies detected prenatal, the genetic counseling must be completed by appropriate support, helping the parents to deal with psychological problems.

The aim of our study was to detect the diagnostic difficulties of gonosomal abnormalities by FISH method in prenatal diagnosis and to identify the genetic counseling issues and bioethical dilemmas in parental couples who have a child with a sex chromosome abnormality.

MATERIAL AND METHODS

This 9-year retrospective study (2004–2012) targeted the gonosomal anomalies identified in the Department of Prenatal Diagnosis of the Iasi "CuzaVoda" Maternity Hospital. Prenatal diagnosis by FISH method in interphase nuclei obtained from amniotic fluid was performed in 1685 pregnant women. Amniocentesis was performed between 16 and 27 weeks of amenorrhea (WA). FISH method used fluorescently labeled DNA probes specific for chromosomes 13, 18, 21, X and Y (AneuVysion Multicolor DNA Probe Kit Vysis CEP 18/X/Y - alpha satellite / LSI 13/21). In 15 cases gonosomal abnormalities were detected or there were difficulties in interpreting the number of fluorescent signals corresponding to the two sex chromosomes: X and Y (tab. I).

RESULTS

Six of our cases showed X monosomy. Five were homogeneous forms (single fluorescent gonosomic signal corresponding to chromosome X) and in the sixth case we found a 45,X/46,XX mosaicism (presence of only one gonosomic fluorescent signal corresponding to X chromosome in 60% of the cells). The evolution of pregnancies was the following: one ended with the birth of a baby girl with Turner syndrome (monosomy X confirmed by postnatal chromosome analysis), three ended in miscarriage (one with cystic hygroma), and two ended in therapeutic abortion due to cystic hygroma. In three cases we found both cells with two fluorescent signals corresponding to X chromosomes and cells with a signal

for chromosome X and a signal for Y chromosome. Pseudomosaicism 46,XX/46, XY was not confirmed by repeat analysis in two cases, proving that the first amniotic fluid samples were contaminated with maternal blood. Both pregnancies ended in normal male babies. In the last case, repeat analysis confirmed the 46,XX/46,XY mosaicism, indicating a true hermaphroditism. The intersex stated was confirmed by anatomopathological examination, the pregnancy ending in miscarriage. In three cases we found a trisomy XXY, the FISH test showing two green signals corresponding to X chromosome and a red signal for Y chromosome. Two pregnancies ended in two baby boys, postnatal chromosome analysis confirming the trisomy XXY. In another case we were faced with one of the limitations of FISH technique in prenatal diagnosis. Thus, although in most fetal cells we detected three fluorescent signals corresponding to gonosomes, we also identified cells with extra small green fluorescent signals. Due to the small number, these cells were interpreted as artefacts. Although the fetus presented choroid plexus cysts, there were no reasons for therapeutic abortion and pregnancy ended with the birth of a baby boy weighing 2750 g and measuring 47 cm in height.

Clinical examination showed microcephaly with scaphocephaly, hypertelorism, epicantus, bilateral cryptorchidism and hypotonia. Postnatal chromosomal analysis revealed mosaicism with 6 cell lines:

48,XY,+mar,+mar/ 47,XY,+mar/48,XY ,r(X),+mar/

49,XY,r(X),+mar,+mar/ 46,XY/50,XY, r(X),r(X),+mar,+mar

The ratio of the six cell lines was: [29]/[14]/[10]/[3]/[3]/[3]. In one case we found a trisomy XYY (a single green signal for chromosome X and two red signals for chromosome Y), the pregnancy ending with the birth of a clinically normal baby boy. Postnatal chromosome analysis disclosed the 47,XYY formula. In two cases we identified three green signals corresponding to X chromosome, but also three fluorescent signals for chromosomes 13, 18 and 21, proving a triploidy: 69,XXX. Both pregnancies were terminated, and the anatomopathological examination revealed fetuses with multiple congenital anomalies and severe intrauterine growth retardation.

DISCUSSION

Globally, gonosomal abnormalities have a high incidence, being the most common chromosomal pathology, affecting 1/500 live births. The most common abnormalities are monosomy X, trisomy X, trisomy XXY and trisomy XYY (4, 5).

Monosomy X was the most common gonosomal abnormality in our group. It affects 1/2500 women and causes Turner syndrome, characterized by short stature, primary amenorrhea, infertility and normal intellectual development in most cases. Although phenotypic changes are not very severe, 90% of fetuses with cystic hygroma and monosomy X shows fetal anasarca, causing spontaneous abortion (10% of spontaneous abortions in the first trimester) (4, 6). The prenatal detection of monosomy X is usually accidental and, due to good integration into society, it is not an indication for therapeutic abortion, except for the cases with cystic hygroma (7). In one of our cases the pregnancy had a normal evolution; the girl has a favorable outcome and benefits from growth hormone therapy.

Trisomy XYY affects 1/1000 boys and is a disease diagnosed fortuitously, because unless high stature and possibly hypo fertil-

ity are present, no other particular clinical signs are present (4, 8). In our case the family decided to keep the pregnancy, which was ended by the birth of a clinically normal baby boy.

Trisomy XXY causes Klinefelter syndrome, the most common cause of male chromosomal infertility. The disease affects 1/1000 boys and is characterized by hypogonadotropichypogonadism, but close to normal intellectual development. Two of the trisomy XXY cases detected by us were homogeneous, and at the time of birth the children showed no clinical manifestations. In the third case we identified a complex mosaicism with six cell lines and additional X chromosome fragments (marker and ring X chromosomes). To diagnose such a case is impossible by using only the FISH technique, the anomaly being mosaic and the marker chromosomes representing X chromosome fragments that do not contain centromeric sequences (the region where the probe corresponding to the chromosome X is attached). Polysomy XY with more than two X chromosomes generates mental retardation and birth defects, features identified in our cases. Also, additional ring X chromosomes induce microcephaly, growth retardation, genital abnormalities and mental retardation (4, 9).

Triploidy, characterized by the presence of an extra haploid set of chromosomes, generates a severely altered phenotype, which usually induces miscarriage (4). In the cases of triploidy diagnosed by FISH technique are identified three fluorescent signals corresponding to the gonosomes, and three signals for chromosomes 13, 18 and 21. Both pregnancies with triploidy in our study showed three signals for X chromosome, and ended in miscarriages, the fetuses presenting multiple congenital anomalies.

In all cases there were some genetic counseling issues (related to the type of chromosomal abnormality) and difficulties in providing psychological support. Communication of an abnormal result in prenatal chromosome analysis is a difficult process, inducing various reactions from the parents: confusion, guilt, anxiety related to child's development and integration into society, helplessness, rejection of the baby. In the first instance, most couples chose termination of a pregnancy with pathological gonosomal abnormalities, even if only minor development features were modified.

Reaction to diagnosis depends on culture, education, religion and economic status of the couple. Overcoming obstacles imposed discussions with parents so that they understood the significance of the diagnosis and took an informed decision about the pregnancy (10, 11, 12). Depending on the evolutionary potential, the pregnancies could be divided into two groups. One group included the cases with trisomy XXY, trisomy XYY and monosomy X without cystic hygroma, characterized by a positive development and satisfactory integration in society. In these cases, during genetic counseling it is explained to the family that there is no reason for therapeutic abortion (10, 11, 12, 13). This strategy was applied by us in our eight such cases. The other group included the cases of triploidy and monosomy X with cystic hygroma. In both situations, the pregnancy has a negative prognosis, ending in a miscarriage with the fetus having multiple congenital anomalies; pregnant women require exceptional attention, particularly when the pregnancy is "special", being obtained after several attempts (7). Thus, the severe progression of the disease should be explained,

with its negative repercussions on the reproductive potential of women, the best option being the therapeutic abortion. In fact, in our cases parental couples have opted for therapeutic abortion, the anatomopathological findings confirming the malformations. In the cases with 46,XX/46,XY pseudomosaicism there were genetic counseling difficulties in the first instance related to accepting the intersex status associated with true hermaphroditism, but repeat tests confirmed the contamination of the first amniotic fluid sample with maternal blood (14).

Another problem we were faced with is the legitimacy of abortion. In Europe there are countries that do not allow abortion (Malta, Ireland), countries that support therapeutic abortion when the fetus has non-viable birth defects or the pregnancy is dangerous for the mother (this approach is applied in Cyprus to 28 WA, 24 WA in Finland and United Kingdom and 22 WA in Spain) and countries that allow abortion on-demand (mostly to 12 WA, except Romania 14 WA, 18 WA in Sweden and 10 WA in Slovenia). In all therapeutic abortion cases, pre-and post-abortion counseling support is necessary (15).

CONCLUSIONS

Our study, aiming to detected gonosomal abnormalities by FISH technique, enabled us on the one hand, to highlight the limits of this type of diagnosis, and on the other hand, to reveal the genetic counseling difficulties. The main limitations are related to the impossibility of correctly quantifying the gonosomal mosaics and interpretation difficulties for some 46,XX/46,XY mosaicism types. Genetic counseling in prenatally detected gonosomal anomalies faces difficulty in convincing the couple that the fetus has a chromosomal abnormality with minor changes in phenotype that allows a normal integration in society, so that they can get over the psychological trauma induced by prenatal diagnosis and choose to maintain the pregnancy. On the other hand, when non-viable abnormalities or with a minimal development potential are identified, the possible negative consequences to maintaining the pregnancy should be objectively presented.

CORTICOSTEROIDS IN TUBERCULOSIS THERAPY

Tuberculosis (TB) is a major public health problem which determining 1.4 million deaths in each year. The steroids as an associated treatment with anti-TB drugs are routinely used for reduce inflammation, only in certain types of TB. Professor Critchley and collaborators from St George's, University of London have made a systematic review and meta-analysis to estimate the steroids capacity for reduced mortality in all forms of tuberculosis. The researchers examined results from 41 previous trials on the efficacy of corticosteroids therapy in some forms of TB (pericarditis, meningitis, peritonitis, pleurisy and pulmonary TB also). Patient's age, the comorbidity, the types, the doses and the duration of corticosteroids therapy have varied. The results show that steroids therapy has reduced mortality by 17%, regardless of the form of tuberculosis or type of anti-TB therapy. However, researchers say that further studies are necessary for the evaluation if the benefits of steroids therapy for all TB forms would outweigh the risk of side effects, especially for multidrug resistant TB cases (Critchley JA, Young F, Orton L. Corticosteroids for prevention of mortality in people with tuberculosis: a systematic review and meta-analysis. *The Lancet Infectious Diseases*, 2013; 13 (3): 223).

MULTIPLE MYELOMA WITH BILATERAL HUMERUS LOCATION CASE REPORT

O. Alexa, B. Veliceasa
University of Medicine and Pharmacy "Grigore T. Popa" – Iasi
Faculty of Medicine
Discipline of Orthopedics and Traumatology

MULTIPLE MYELOMA WITH BILATERAL HUMERAL LOCATION: CASE REPORT (Abstract): Multiple myeloma, also known as Kahler's disease or myelomatosis, is a type of cancer that begins in plasma cells. It is the second most common hematologic malignancy (13%) and accounts for 1% of all cancers. A mnemonic sometimes used to remember the common tetrad of multiple myeloma is *CRAB*: C = Calcium (elevated), R = Renal failure, A = Anemia, B = Bone lesions. **Case report**: We present the case of an 70- year-old male with bilateral humeral location. Diagnosis was difficult because of atypical X-ray findings in the right shoulder, the classic finding being punched-out lesions. ESR, blood, renal and liver tests were atypical. **Conclusion**: Although the diagnosis of multiple myeloma is easy, being based on blood and kidney tests and X-ray examination, in some cases an accurate diagnosis is obtained only by pathological examination. **Keywords:** MULTIPLE MYELOMA, PLASMA CELLS, HUMERUS.

Multiple myeloma (MM) is a cancer of plasma B cells, also known as Kahler's disease or myelomatosis. It is the second most common hematologic cancer (13%) and accounts for 1% of all cancers (1).

The exact cause of multiple myeloma is not known, and most myeloma patients are elderly.

It is located in the bone marrow, especially in the vertebrae, ribs, skull, pelvis and femur and is accompanied by numerous clinical manifestations including anemia, bone lesions, hypercalcemia, renal dysfunction and compromised immune function. A mnemonic sometimes used to remember the common tetrad of multiple myeloma is *CRAB*: C = Calcium (elevated), R = Renal failure, A = Anemia, B = Bone lesions" (2).

Diagnosis is based on the presence of neoplastic plasma cells in the bone marrow or elsewhere extramedullary together with the presence of multiorgan dysfunctions.

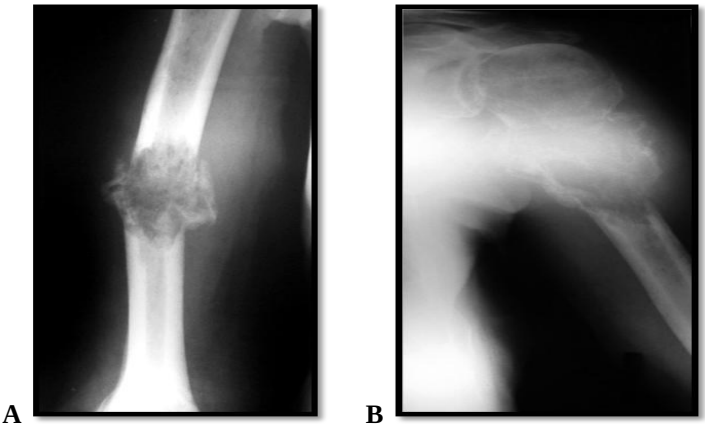
CASE REPORT

Patient, aged 70 years, reported about two months earlier a traction injury of the left upper limb and about 1.5 months ago one of the right upper limb for which he presented at the Câmpulung Moldovenesc Hospital, Suceava County, where he was diagnosed with pathological fracture of the middle third of the right humeral shaft and of the proximal third of the left humeral shaft, both treated by plaster splint. Because after about two months both fractures were not consolidated, the patient was referred to our department.

The patient underwent laryngeal surgery

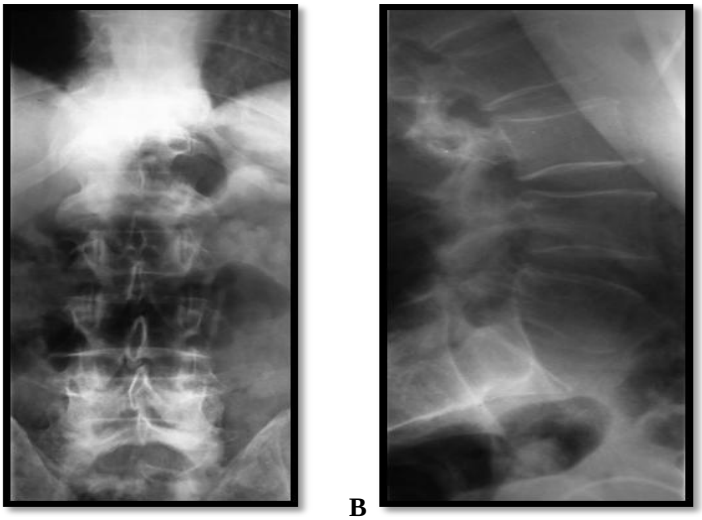
30 years ago and surgical removal of a rib segment about 15 years ago, but was unable to provide detailed information. The patient had a first-degree relative with leukemia.

Physical examination showed an increase in volume of the left shoulder and right arm in the middle third. Radiographs showed in the right humerus a relatively well-defined osteolytic area of approximately 30 mm accompanied by fracture (fig. 1A), and in the left humerus a poorly-defined osteolytic area covering the entire proximal humeral epiphysis, with moderate periosteal reaction and extension to the neighboring soft tissues (fig. 1B). Thoracic radiography showed the absence of the lateral arch of the VIII-th right rib of about 8 cm, and lumbar column radiography revealed no osteolytic lesions (fig. 2). Abdominal and pelvic ultrasound revealed hepatic steatosis, homogeneous spleen and prostatic hypertrophy.



A **B**

Fig. 1. X-ray - anterior-posterior view: A – right arm, B – left shoulder



A **B**

Fig. 2. Lumbar column X-ray,: A – anterior-posterior view, B – lateral view

Laboratory tests detected a slight increase in granulocyte count (70,1/%), moderately increased ESR (16 mm/h); total proteins and the other biological tests were normal.

Scintigraphy revealed hyperfixing sites projected in areas of the middle 1/3 of the right humeral shaft, proximal third of the left humerus, very heterogeneous, which appeared to exceed the bone contour. It also detected linear hyperfixed areas at the level of the xiphoid appendix; moderate hyperfixing sites in the posterior arches of the CIX and CX right ribs; heterogeneous hyperfixing in the lumbar spine with moderate hyperfixing al the level of the right costovertebral joints CVIII, CIX and CX. It was concluded that in the context of recent trauma and in the absence of other pathological hyperfixing sites, a traumatic etiology seemed more likely but a tumoral etiology could not be ruled out. (fig. 3).

Contrast enhanced MRI showed the presence of an expansive, solid, heterogeneous formation in the upper third of the left humerus, which disrupted the bone cortical with invasion of the brachial biceps and triceps muscles; with invasion of the left scapula, mainly the superficial muscle plane (supra and infraspinatus muscles), and subscapular muscle (fig. 4A). In the right humerus multiple well-defined sites of "gadolinophilic" lesions of 2 to 30 mm, disseminated intraosseously in the upper two-thirds were seen (fig. 4B).

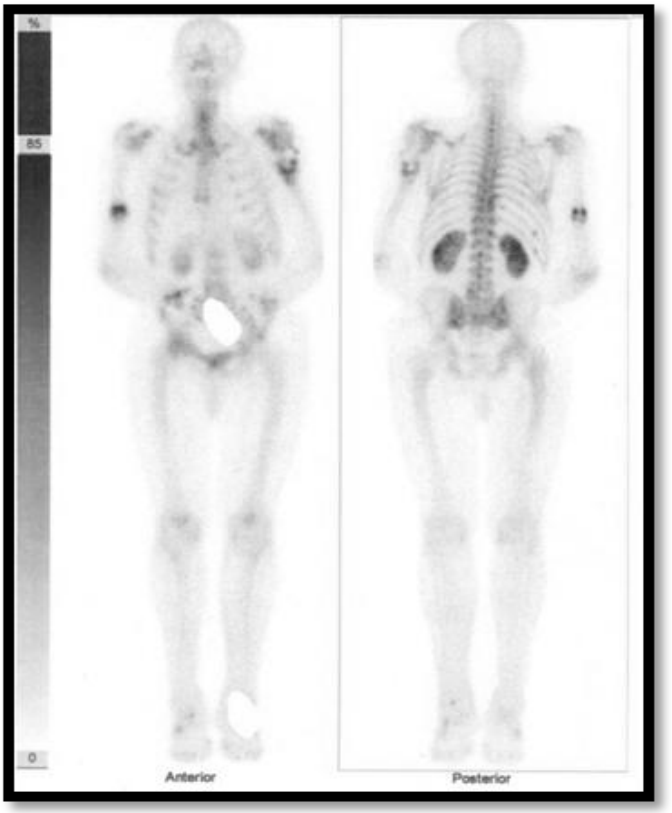


Fig. 3. Bone scan - full body.

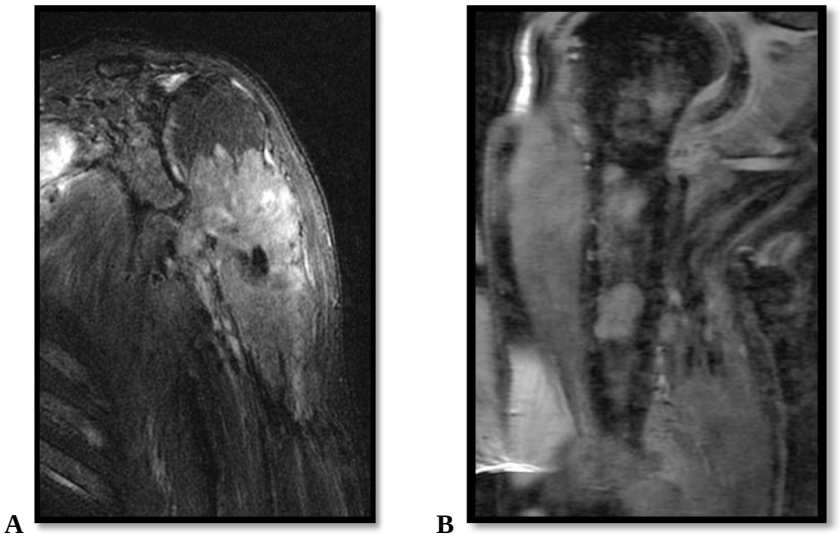

Fig. 4. Contrast enhanced MRI: A – left shoulder; B – right arm.

Pathological examination of hematoxylin-eosin stained slides revealed bone tissue of osteolytic appearance and tumor fragments consisting of a monomorphic plasma cell population, which, in the left humerus, also infiltrated the muscle, these findings being conclusive for the diagnosis of multiple myeloma.

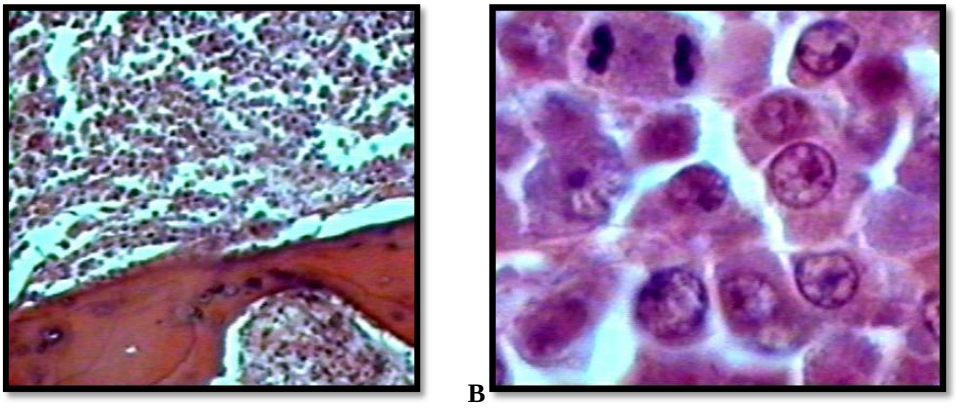

Fig. 5. Multiple myeloma, H & E staining (A - Ob. 20x, B – Ob. 90x)

DISCUSSION

The most common locations of MM include the ribs, vertebrae, pelvis and skull cap (3). In our case it was located in the humerus.

In our patient the diagnosis was difficult due to the development of an atypical radiologic image picture in the left shoulder; radiologically, MM is characterized by the presence of "punched-out" osteolytic lesions prevalently located in the shaft of long bones (4).

MM diagnosis can be made with pretty much certainty on the basis of laboratory tests. In our case these were not conclusive enough. MM is characterized by normochromic anemia, normocytic anemia, elevated ESR, hypercalcemia, elevated serum proteins, Bence-Jones protein in urine + (5), while our patient presented only a slight increase in granulocyte counts (70,1/%) and a moderately increased ESR (16 mm/h), kidney and liver tests being normal.

In our patient, diagnostic certainty came from pathological examination performed on tissue biopsy taken from the left shoulder and proximal third of the right humerus.

MM is a malignant neoplasm of plasma cells that remains incurable by conventional chemotherapy, median survival being 2-3 years (6). It is usually chemosensitive, but frequently enters a plateau phase of variable duration (6).

The presented case had an atypical progression with quite important extramedullary extension. The cases with extraosseous extension of an intramedullary tumor nodule as a result of cortical erosion and subsequent spread beyond the periosteum are not rare, bur soft tissues involvement is exceptional occurring in rare forms of IgD MM (7).

PATHOLOGY OF THE OPTIC NERVE INJURY (Abstract): The optic nerve injury is produced by damaging the optic nerve within a craniocerebral trauma. The anatomo-pathology and the pathology of posttraumatic visual impairments are fundamental data for the therapeutic indications. The microscopic examination reveals only the particular cases of very serious or severe extensive lesions. Damage to the vessels of the optic nerve, damage and break of the optical fibers are responsible for immediate visual impairments and secondary hematomas and edemas involving. The factors for the late appearance of visual impairments are numerous and often confounding. **Material and methods:** In the present research, we have a female patient D.A., aged 29, diagnosed with closed fracture in the right frontal lobe, irradiated to the optic canal; blindness in the right eye. **Results:** Break of the optical fibers is a result of bone fragments or of traction and torsion. Damage to the vessels of the optic nerve represents the main cause of blindness for most authors. Traction and torsion of the vessels at the moment of injury may cause thrombosis and small hemorrhages which lead to severe ischemia of the optical fibers. **Conclusions**: The optic nerve injury is produced by damaging the optic nerve within a craniocerebral trauma, through an indirect mechanism most of the times. **Keywords:** CRANIOCEREBRAL TRAUMA, OPTIC NERVE, VISUAL IMPAIRMENTS

The optic nerve injury is produced by damaging of the optic nerve within a craniocerebral trauma. The microscopic examination reveals only the particular cases of very serious or extensive lesions; the anatomical and clinical examination is usually missing. Only the neurosurgical intervention undergone in order to explore the nerve can provide information macroscopically (1, 2).

The macroscopic examination finds specific relations by highlighting cause and effect, but sometimes the examination undergone during the surgical intervention is incomplete; moreover, opening the optic nerve sheath is rarely in the literature (3, 4, 5).

There are several causes distinguished of immediate and late visual impairment. Immediate visual impairments are divided, clinically speaking, into complete and partial impairments. Within the optic nerve traumas the main cause that can be associated with different degrees is *optic nerve damage* - can be a bone injury as a conse-

quence of an injury to the optic canal or a direct injury. The direct injury to the optic nerve is visible; it can be a result of a foreign body or it can occur as a result of bone fractures. Optic nerve injury by fracturing the canal has a frequency which varies according to different authors: Rollet, Paufique, Barkan, Lazorthes (1, 3) consider them to be frequent injuries; Wagemann, Berlin, Strieff, Genet and Turner (7, 8) insist on the rare occurrence of this type of injury. This disagreement occurs because of insufficient radiologic examinations and due to the fact that some patients underwent a surgery while others were treated medically.

It is important to establish the cause-effect relationship between the bone fracture and the injury to the optic nerve. The opinions are different. In some cases, the cause effect relationship is obvious: the nerve is compressed by bone fracture in the canal area, the canal and the nerve are displaced, and bone fragments penetrate the nerve while the sheaths are breaking down – a fracture without an evident displacement (6, 7, 8).

According to other authors (9, 10), the optic canal frequently has a very small and reversible deformation due to a flattened diameter. These deformations can also be permanent as some radiographies show it – they can injure the optic nerve. In rare cases, the bone lesions accompany the optic nerve injuries without being the causal factor.

MATERIAL AND METHODS

The female patient D.A., aged 29, has the following diagnosis: - closed fracture in the right frontal lobe, irradiated to the optic canal; blindness in the right eye; right frontal flap, disease of the scalp skin; bone flap with lateral pedicle; lumbar puncture with convenient intracranial hypotension. Dura mater is separated from the roof to the little wing along which a fracture is found parallel to the posterior border unfolding into numerous fragments together with the inferior, superior and external fragment. It follows frontal ablation of the orbital roof and bone fragment compression and 75 % of the circumference of the optic canal is liberated. Inside, an ethmoid cell is opened and many bone fragments are found inside; these fragments are ablated.

RESULTS AND DISCUSSION

The ethmoid cell is obstructed. Haemostasis is assured. The dura is suspended and the anatomical plans are restored. The diagnosis is established intraoperative; interruption of the right optic nerve syndrome; frontal vault fractures irradiated to the optic canal.

Break of the optical fibers are a result of bone fragments or of traction and torsion. Minassian (4) reported a case of injury to the optic nerve without fracturing the canal. Nucci et al. (6) makes the assumption that there may be optic nerve contusions with interrupted nerve fibers caused by the relative motion of the encephalon in the skull, producing tractions and torsions at the level of optic canal and junction areas. Nevertheless, this hypothesis cannot be demonstrated surgically.

Damage to the vessels of the optic nerve represents the main cause of blindness for most authors (7, 8). Traction and torsion of the vessels at the moment of injury may cause thrombosis and small hemorrhages which lead to severe ischemia of the optical fibers.

Functional disturbances of the optic nerve generate general physico-pathological reactions and some spontaneous remissions

of immediate blindness can be explained. These functional disorders are in connection with the blocking of subdural and subarachoid space; this way, the passing of fluid along the nerve is prevented; the flow of the fluid elements can be restored only after the decompression of these inextensible areas – the optic canal and Zinn's ligament, accordingly.

Castros (6) claims that immediate visual impairments can also occur within the traumatic retinal angiopathy through venous reflux (Purtscher's retinitis) and due to retinal posttraumatic ischemic syndrome, through central retinal artery thrombosis.

Secondary appearance of impairments or blindness is a consequence of the initial perturbations, but which lack clinical expression or the examination does not reveal it. Hematomas can lie inside three levels: inside the duramater and extradural, inside the subdural space and in the optic nerve. These hematomas are frequent inside the subdural space; they do not have specific limits and are easily evacuated. Subdural hematoma or sheath hematoma can stretch along the walls of the nerve, and this may cause severe compromised vascularization; hematic compressive lesions may lead to necrosis of nerve substance; it may also lead to thrombosis of small vessels of piamater. The arterioles break in the vaginal space may produce intra-nervous hematomas; they can organize themselves in order to produce fibrotic glial tissue and adjacent necrosis. These intravenous hematomas can explain the unsystematised amputations of the visual field (6, 7).

Edemas apparently seem that are early lesions and not immediate ones. Juge (4) finds cases in which edemas appear 3 months after the initial trauma. Due to the rigidity of the bone canal, the edema causes a veritable nerve strangulation, so that during the decompression it can be seen the trace left on the nerve sheath. In edematous forms, the postoperative treatment with corticosteroids is compulsory.

Late impairments are often unknown due to the fact that they evolve gradually and they are clinically latent. These forms have a certain importance because they get good results after the surgical intervention.

Gliosis scar tissue is consecutive to the attrition of the optical fibers and nerves' vessels and they are represented, at least at the beginning, by histological repairs of the damage. New lesions are produced due to the fact that these scarring processes can extend.

Perioptic arachnoiditis were described by Marinescu and Cazaban (3). They can occur in nervous system disorders, traumas, tumors and infections, and the general conditions of the body (intoxications, infections, especially facial cavities infections). Arachnoid neoformations form a construction of the nervous tissue and they tend to comprise the optic nerve and chiasm. Sometimes incisures can be seen as a result of the strangulation of the optic nerve or chiasm. So, the adhesions press the nervous tissue transacting it. At the same time, the circulation is disturbed: the arteries appear to be atrophic, the flow in the arterial circulation is diminished; the veins are dilated and congested, so the return flow is not normal. The mechanic and vascular elements contribute to the anatomic and functional alteration of the nervous cells.

Chronic swelling of the nerve – it was reported in other observations (8, 10).

Progressive development of a bone callus is an exceptional lesion. Streiff (4) cited a case where the diagnosis was established

radiologically, 5 years after the trauma took place, even if the patient had lost his vision immediately after the injury. Functional disturbances of the optic fibers or of the vascularisation of the nerve – it seems that they play an important role. Also cavernous carotid aneurysms, according to Brihaye (6) or ophthalmic artery aneurysm were detected.

CONCLUSIONS

The optic nerve injury is produced by damaging the optic nerve within a craniocerebral trauma, through an indirect mechanism most of the times. In these cases, the fracture of the skull base, with or without the involvement of the optic canal, determines immediate bilateral or unilateral blindness, stationary or slightly regressive. The fracture trajectory may or may be not visible through imagistic diagnosis at the level of the canal or the optical hole, and it is not compulsory to have dilacerated or compressive bone fragments.

SEVERE ENTEROVIRAL ENCEPHALITIS COMPLICATED BY ENCEPHALOMALACIA - CASE PRESENTATION

Anca Georgescu, Carmen Chiriac, Brînduşa Ţilea, Iringo Kezdi
University of Medicine and Pharmacy - Târgu Mureş
School of Medicine
Department of Infectious Diseases

SEVERE ENTEROVIRAL ENCEPHALITIS COMPLICATED BY ENCEPHALOMALACIA - CASE PRESENTATION (Abstract): Enteroviral encephalitis is a rare neuroinfection more often diagnosed in children within the context of enteroviral epidemic outbreaks. It has pleomorphic clinical features, variable severity and a definite potential to cause neuropsychological sequelae especially in infants. Some subtypes are extremely severe with a mortality rate of up to 25% by affecting the brain stem. These subtypes usually come with highly specific neuroimagistic findings. We are presenting a paediatric case of diffuse encephalitis most likely enteroviral in nature, with some particular features concerning the severe clinical form, the neuroimagistic aspects and the neuropsychological sequelae due to the rarely described evolution towards encephalomalacia. **Key words**: ENTEROVIRUS, ENCEPHALITIS, ENCEPHALOMALACIA.

Acute encephalitis is a rare manifestation of infection with enteroviruses, causing less than 5% of all encephalitis (1). The most widespread form is that of common, diffuse encephalitis, with sudden onset within 3 days after prodrome, with hyperpyrexia syndrome of intracranial hypertension, seizures impaired sensorimotor leading to apathy, lethargy, and coma. The focal forms occur before the age of 18 months, associated with partial seizures, hemichorea, ataxia and they generally have a minimal correspondent imaging (2,3). Severe damage to the brainstem by some strains, to neurogenic pulmonary edema, is described as being associated with certain epidemic outbreaks, with a mortality of 25% (4). Accurate diagnosis is conferred by virus isolation from cerebrospinal fluid (CSF), brain tissue, or possibly from other sites, accepting the serological diagnosis as well. Ultrasound examination is extremely valuable in locating specific lesions (5).

CASE PRESENTATION

A 3-year old patient without a significant pathological history, properly vaccinated for her age, having a sudden onset of the disease 48 hours before admission, with a temperature of 38°C, accompanied by an episode of tonicoclonical seizures which lasted for 2 minutes. The pediatrician sets the diagnosis, that of herpangina, and recommends treatment at home, and further neuropsychiatric evaluation. After 24 hours, the patient presents vomiting, has a seizure episode lasting for 30 minutes, accompanied by emission of urine, which is slowly cupped with intravenous Diazepam. She is admitted to the Infectious Disease

Clinic on the 29th of May 2011, suspected with acute meningoencephalitis.Admission examination. Influenced malaise, low grade fever 37.8°C, drowsy (after administration of Diazepam), active attitude, stature-weight hypotrophy, pale facies, erythematous pharynx with microvesicles and ulcer on the posterior wall, stethacoustic pulmonary vesicular murmur, pulse rate (PR) 104 beats/ min, liver palpable at 1 cm below the right costal part, absent meningeal irritation syndrome, unreleased abdominal skin reflexes on the right, more reduced osteotendinous reflexes (OTR) on the level of the right lower limb. Laboratory analysis revealed no biological inflammatory syndrome, the absence of haematologic, liver or kidney disorders, repeated negative serology for HIV, herpes simplex virus and Borrelia burgdorferi. Anti-enterovirus IgM antibodies showed a positive value in the second week of hospitalization 12.65 U, with values rising after another week (13.30 U).

Laboratory investigations

Fundus examination (FE) on admission shows papilla with vaguely defined borders, an aspect that is maintained for six weeks. Chest X-ray: emphasised broncho-vascular hilo-basal scanning on the right side. Lingual secretion: *Candida albicans* sensitive to fluconazole.

Initial examination by cranial computer tomography (CT) (29th of May 2011) does not reveal heterodense intracerebral lesions. Examination by multiplanar magnetic resonance imaging (cranial MRI) (31st of May 2011) in dual weight discretely reveals a T2 hypersignal and a T2- flair and a diffuse T1 hyposignal, by deleting the left temporal lobe and left parietal plot, suggesting the onset of encephalitis; symmetrical ventricular system, in the midline, basal cisterns without pathological modifications of signal (fig. 1).

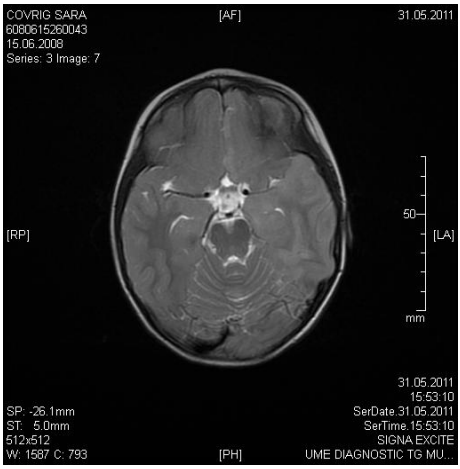

Fig. 1. IRM cranian 31.05.2011

Cranial CT (24th of June 2011): large areas of digitiform hypodensity, with net, hyperdense contours, data given by the affected gyri (cortical) located on the basal front and left parietal part. No spontaneous hyperdense accumulation on the level of the brain substance and subarachnoid space was present. Cerebral atrophy, increase in the size of the basal cisterns (fig. 2).

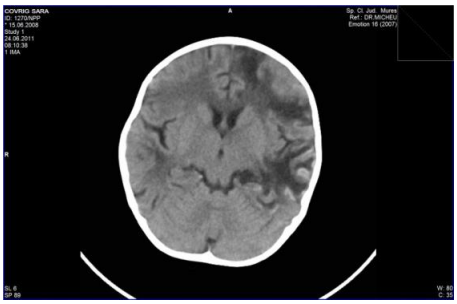

Fig. 2. CT cranian 24.06.2011

Cranial MRI (21st of July 2011): extensive damage in T2 hypersignal and T1 hyposignal detected in both cerebral hemispheres, suggesting an encephalomalacia in the context of meningoencephalitis. Poste-

rior fossa structures and basal ganglia seem less affected (fig. 3).

Fig. 3. IRM craniu 21.07.2011

Other investigations

Pediatric neuropsychiatric examination (PNE) (31st of May 2011): Superficial comatose status, medication. Suspected encephalitis. Secondary generalized focal seizures. Re-evaluation of the PNE (17th of June 2011): severe, acute meningoencephalitis. Convulsive syndrome, with secondary generalised focal motor seizures. Motor aphasia. Flaccid quadriparesis with predominant right hemiparesis; 1st of July 2011: severe acute meningoencephalitis. Flaccid right hemiparesis. Papilloedema. Motor aphasia. Right facial palsy of central type.

Electroencephalographic examination (EEG) (the 6th of July 2011): Diffuse hypovolted route for that age, a delta-theta background, with regular pseudorhythmic discharges of Radermecker-like complex.

Positive diagnosis

Severe acute encephalitis, probably having the aetiology of an enterovirus, complicated by encephalomalacia. Flaccid quadricparesis with predominant hemiparesis on the right. Right facial palsy of central type. Mixed aphasia. Symptomatic focal epilepsy with secondary generalized seizures. Severe neuropsychomotor setback. Herpangina. Oral candidiasis. Positive aetiologic diagnosis is difficult to be sustained, without CSF examination, which was contraindicated because of the FO results, and which would have allowed in the acute phase of the illness, its accurate assertion, by identifying the ideal viral RNA, or that of acute phase anti-Enterovirus antibodies, and also the evaluation in order to determine the presence of meningina and the constant inflammatory changes. Differentiation required by the major focal manifestations of herpetic aetiology, with much higher incidence in these forms, but without a medical history, suggestive clinical data and specific positive serology was denied. Enterovirus aetiology is supported by epidemiological data - regional epidemic context represented by suggestive clinical diagnosis (hand-foot-mouth disease, herpangina, diarrhoeal diseases) in summer, by clinical data - herpangina concomitance, and Ig M positive serology, with frowing values.

Treatment

Steroidal anti-inflammatory treatment with Solu-Medrol, Dexamethasone, Hydrocortisone hemisuccinate, depletion with Mannitol, Furosemide, Spironolactone, glycerol, Acetazolamide, intravenous Immunoglobulin (Humaglobin, Flebogamma) 10 days; antiviral treatment with Virolex for 14 days and antibiotics in the first 10 days; anticonvulsant therapy with Diazepam during seizures, with dose reduction in parallel with the introduction of Depakine, Phenobarbital. Anxiolytic therapy during the severe periods of turmoil and antisecretory neuroroborants.

Evolution

The immediate evolution was rapidly unfavourable by secondary generalised

seizures of the limbs, followed by temporary hemiparesis on the right and right facial paresis of central type, profound coma GCS 3/15 for 72 hours.

On awakening, the patient showed signs of increased focus, mixed aphasia, apathy, lack of communication. Neuropsychological decline was continuous, with progressive installation of other signs of brainstem involvement (nystagmus, divergent strabismus, significant problems with swallowing), ataxia, myoclonus, intentional tremor, choreoathetosis movements on the right hemibody, ocular deviation to the right, lethargy together with the progression of brain lesions visible on the ultrasound images, evolutionary aspect to encephalomalacia up to 5 weeks after onset, during which the patient remained feverish. The patient is hospitalized in a pediatric neurology clinic for neuropsychomotor recovery; the neuropsychomotor level was initially evaluated to 5-6 months, the psychic to 9-10 months, the 10-12 weeks of illness scoring the peak of the neuropsychomotor regression. On a long-term basis the evolution was slow but favorable, with improved muscle tone, eye contact, active motility resumption, independent movement, individual feeding with solid food, the utterance of a few words. The current neuropsychomotor level is of 18-20 months, the psyche of 15-16 months. The ophthalmologic evaluation (October 2011) revealed bilateral elongated visual potential, with normal amplitude, suggesting bilateral affection of the optical paths. The last EEG shows a theta background, hypovolted on the bilateral OP leads and left central part, large and front (F) right part irritative with continuous CVU discharges, poliVU, confounding with the current slow CVU/ poliVU and F right side as paroxysmal discharges, and hypervolted theta waves - worse aspect than the previous one.

MRI examination (April 2012) describes multiple porencephalitic bihemispherical areas, predominantly on the left side, showing a T2 hypersignal, FLAIR and T1 hyposignal, minimal perilesional residual edema, right frontal hypersignal cortical areas and occipital bilateral, a moderate ventricular system/ severely asymmetrical, the left ventricle being more dilated (fig. 4).

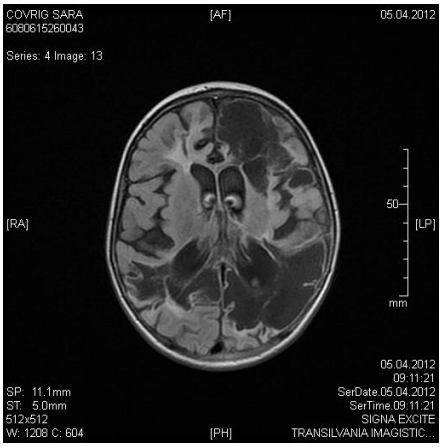

Fig. 4. MRI cranial 05.04.2012

In April 2012 it was possible to perform lumbar puncture and to collect CSF, in which, the examination for Plex-ID virus was negative.

DISCUSSION

The severity of the enteroviral encephalitis is variable, potentially causing neurological sequelae in infants, but with full psychomotor restitution after this age (1). The standard in establishing the etiological diagnosis is to isolate the virus through polymerase chain reaction (PCR) from the brain tissue or CSF (1.6).

The neuro-imaging appearance caused by some serotypes, the latest one being the EV71, led some of the authors to take into consideration the damage of the posterior

structures of the bulb, bridge, mid-brain and dentate cerebellar nuclei in severe cases and anterior horns of the spinal cord and that of the supratentorial nuclei (5) .

The evolution to cavitation and the development of encephalomalacia has been sporadically described, with little reference: marrow and brain stem encephalomalacia after severe rhombencephalitis in the case of two children, two newborns with wide cystic lesions, and with fronto-parieto-occipital distribution respectively (5.7).

On the other hand, there are reports of atypical localization of the inflammatory process in the hippocampus, imposing the differentiation of herpetic etiology (8). The aspect of the MRI was meticulous through the localization of the initial, unilateral and temporal inflammatory modifications, with cavitary degeneration and progressive, bilateral, fronto-occipital extension.

Persistence at 3 months of the lesions with T2 hypersignal and T1 hyposignal confirm their irreversibility data signals, which are associated with particular forms of severity (9). The negative CSF virological result after 11 months is normal. The possibility of a negative PCR test of CSF, when there is a lack of meningeal disturbance, is highly possible according to some reports. (4.7).

CONCLUSIONS

The patient had acute severe diffuse encephalitis affecting the brainstem as well, the etiology of which was likely enteroviral. The accurate diagnosis by confirming the presence of the viral RNA by PCR was inaccessible at that time, the method being very expensive. Clinical manifestations, although the symptoms described are identical to those presented in the literature, are astonishing because of their severity, extension and malevolent development to encephalomalacia and disabling neuropsychiatric screen, atypical after infancy. Although rare, enteroviruses are able to induce progression to encephalomalacia with diffuse localization, requiring differentiation of herpetic etiology. The contribution of diagnostic imaging is essential in monitoring the severe cases of neuroinfections.

EARLY RESULTS OF THE SURGICAL MANAGEMENT OF GASTROINTESTINAL STROMAL TUMORS (GIST) – THE EXPERIENCE OF THE 3rd SURGICAL UNIT. (Abstract): This study provides a clinical and paraclinical algorithm of assessment of gastrointestinal stromal tumors (GIST), with the possibilities and limits of their current management. It is focused on defining an optimal imaging and anatomoclinic diagnosis protocol. In the absence of specific algorithm of surgical management, the study proposes an evaluation of possible histologic diagnosis and the indication for surgery, and the assessing the immediate results of thesurgical treatment. **Materials and methods.** A retrospective analysis was carried out over a period of 8 years (2004-2011), including patients with pathologic results of resection specimens revealing the stromal nature. There were analyzed the tumor characteristics, the association with other digestive tumors, the biologic behavior, clinical manifestations and the comorbidities of the patient, the indication for surgery, and also, the surgical morbidity and mortality. From 2004 to 2011 there have been operated 24 cases of GIST diagnosed histologically by common stains. Among them, a total of 16 patients (beginning with 2007) were confirmed immunohistochemicaly. **Results.** During the study, each clinical suspicion of GIST was an opportunity for thorough assessment of the clinical picture, imaging studies or anatomoclinical aspects (intraoperative macroscopical aspects, pathological and immunhistochemical examination). We have tried a standardization of diagnostic and therapeutic algorithm. Positive diagnosis of GIST was clinicaly suspected in patients with digestive tract tumors (22 cases out of 24) without mucosal involvement, or based on intraoperative macroscopic appearance. The lesions were confirmed by the pathologist. The surgical morbidity (4 cases - 16.6%), was to the surgery (a single case of anastomotic leakage) or due to patient's comorbidities (diabetus, chronic renal failure, etc), and has been framed to acceptable extent. No deaths occurred in relation to the surgery. **Conclusions.** The diagnostic difficulties are overcome in terms of a positive laboratory features revealed by immunhistochemical examination. The surgical approach of GIST is different from that of a carcinoma. The postoperative immunhistochemical confirmation of GIST , leads the patient to a specific adjuvant treatment. **Key words:** STROMAL TUMOR, SURGICAL MANAGEMENT, IMUNOHISTOCHEMISTRY

Tumorile stromale gastrointestinale (GIST) sunt cele mai frecvente tumori mezenchimale ale tractului digestiv. Se dezvoltă din celule precursoare intestinale (celule Cajal), recunoscute ca pacemaker al peristaltismului intestinal. Majoritatea tumorilor stromale sunt descoperite incidental, cu ocazia laparotomiilor/laparoscopiilor pentru diferite afecțiuni chirurgicale. Caracterele clinicopatologice ale acestor tumori sunt neclare. Modalitățile de diagnostic clinic şi paraclinic (imagistic, laborator) sunt la latitudinea clinicianului, deoarece nu sunt elaborate protocoale (algoritmuri) specifice. Diagnosticul anatomopatologic convențional (pozitiv şi diferențial) este de asemenea dificil şi nu constituie un argument suficient de diferențiere de alte tumori de origine conjunctivă. Fiecare localizare tumorală prezintă particularități de indicație operatorie. Rezultatele tratamentului sunt variabile.

Obiectivul acestui studiu este de a evidenția dificultățile de diagnostic pozitiv şi diferențial al tumorilor stromale, de a confirma fezabilitatea unui act terapeutic chirurgical radical, cu particularități pentru GIST şi de a demonstra importanța unui diagnostic de certitudine pentru a putea orienta ulterior pacientul către un tratament adjuvant specific.

MATERIAL ŞI METODE

În perioada 2004-2011 au fost operate 24 cazuri de tumori stromale gastrointestinale (GIST) diagnosticate histologic prin colorații uzuale; dintre acestea, un număr de 16 cazuri (începând cu anul 2007, de când kit-urile de imunhistochimie au devenit disponibile) au fost confirmate imunohistochimic. Incidența tumorilor stromale a fost mai mare la sexul masculin (F/B=8/16). Vârsta pacienților a fost cuprinsă între 43 şi 81 ani, cu o medie de 61 ani, cu proveniența majoritar rurală (rural/urban= 16/8). Înrolarea pacienților în studiu a fost făcută retrospectiv, utilizînd datele din foile de observație şi din buletinele anatomopatologice în care figura diagnosticul de tumoră stromală gastrointestinală.

REZULTATE

Simptomatologia a fost dominată de scăderea ponderală, sindromul anemic şi durerile abdominale. În afara acestei triade clinice, au mai fost notate şi alte semne şi simptome precum sindromul dispeptic intestinal, ocluzia intestinală, mai rar hemoragia digestivă, sau o tumoră abdominală palpabilă. Un număr de trei cazuri au fost asimptomatice, descoperirea tumorii fiind întîmplătoare, cu ocazia unei laparotomii pentru o altă patologie abdominală. La un singur pacient s-a descoperit asociat unei tumori stromale gastrice un hemoperitoneu în cantitate medie prin ruptura spontană a tumorii (tab. I).

TABELUL I

Simptomatologia clinică a pacientilor cu GIST

Simptomatologie	Nr. cazuri
Scadere ponderală	13
Sindrom dureros abdominal	10
Sindrom anemic	8
Tumoră abdominală palpabilă	6
Hemoragie digestivă	4
Ocluzie intestinală	3
Asimptomatice – descoperire intraoperatorie	3
Sindrom dispeptic biliopancreatic	2
Hemoperitoneu	1

Explorările imagistice au precizat detalii de topografie, dimensiuni, rapoarte anatomice, elemente care au fost coroborate cu

datele clinice şi de laborator, pentru un management chirurgical adecvat, particularizat fiecărui caz în parte. Ecografia, explorare aplicată la toți pacienții, a sugerat la 13 din 24 de cazuri diagnosticul probabil de tumora stromală, în timp ce tomografia computerizată (TC) cu aplicație mai restrînsă, a stabilit un diagnostic probabil de GIST la toți cei patru pacienți care au beneficiat de aportul acesteia (tab. II).

TABELUL II
Investigații imagistice

Procedura	Nr total	Rezultate pozitive	Procent
Ecografie	24	13	54,2%
Endoscopie digestiva	18	7	38,8
Irigografie	7	1	14,2
Tranzit baritat	6	3	50%
Tomografie computerizată	4	4	100%
Rx abdominală simplă	3	1	33,3%
Videocapsula	1	0	0%

Caracterul predominant expansiv al tumorii, absența adenopatiilor locale sau regionale au fost principalele elemente precizate la explorările imagistice. Endoscopia digestivă superioară sau inferioară au evidențiat tumori de perete gastric sau colonic, acoperite de mucoasă integră. La tumorile de mari dimensiuni, producând îngustarea de diferite grade a lumenului digestiv, mucoasa prezenta ulcerație. Aspectele endoscopice au fost confirmate de radioscopiile baritate. Pentru localizările la nivelul intestinului subțire au fost utilizate tranzitul baritat şi videocapsula.

Aspectul macroscopic al tumorilor a fost particular: în general se observă o tumoră cu suprafața lobulată (fig. 1.a), lucioasă, galben-brun, netedă, ce bombează seroasa organului digestiv, iar la nivelul mucoasei, şterge pliurile. La toate tumorile în stadii avansate (14 cazuri) organele vecine sau marele epiploon erau aderente la tumora. Tumorile stromale descoperite au fost în general unice, cu dimensiuni variabile. La un singur caz au fost evidențiate tumori multiple jejunale, de dimensiuni mici (fig. 1.b), iar in alt caz, tumora stromală colon cu invaginație (fig 1.c).

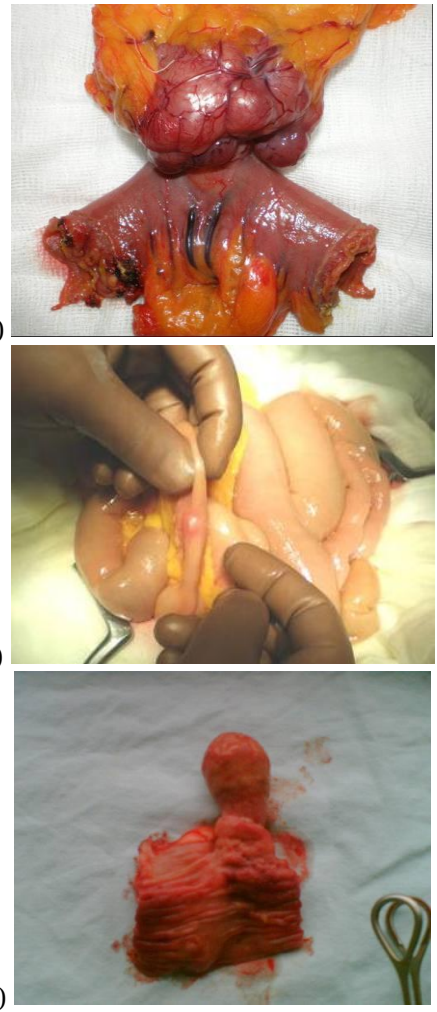

Fig 1 a) tumoră stromală jejun proximal, b) tumoră stromală ileon, c) tumoră stromală colon sigmoid, cu invaginație.

Examinarea microscopică în colorație hematoxilină-eozină a descris o proliferare tumorală de tip conjunctiv ce ocupă submucoasa şi care, în majoritatea cazurilor, se insinuează şi disociază stratul muscular neted, în distribuție compactă sau fasciculat. Orice tumoră conjunctivă a tubului digestiv poate ascunde o tumoră stromală gastrointestinală. În colorațiile obişnuite o tumoră stromală poate mima o tumoră musculară, o tumoră nervoasă sau chiar una epitelială. Pentru confirmarea tumorilor stromale a fost utilizată o baterie standard de teste imunhistochimice: Vimentin (atestă originea conjunctivă a tumorii) şi CD117 (c Kit - marker specific tumorilor stromale). Sunt aplicate şi teste complementare: CD 34 (alt marker specific tumorilor stromale, pozitiv în majoritatea cazurilor), αSMA (actina de muşchi neted- pozitivă în 30-40% din cazuri), proteina S100 (atestă originea nervoasă a tumorii - utilizat mai ales pentru diagnostic diferențial), şi Ki67 (defineşte comportamentul biologic malign sau benign, în funcție de pozitivitate). Rezultatele marcajului imunologic complet la 8 din cei 24 pacienți, sunt prezentate în tabelul III.

Diagnosticul pozitiv anatomopatologic presupune identificarea celulelor Cajal. Importanța marcajului pentru CD 117 şi CD 34 rezultă din faptul că intensitatea imunomarcajului pentru CD117 este corelată direct proporțional cu răspunsul la terapia cu Glivec (Imatinib).

Un alt element anatomopatologic cu valoare prognostica este marcajul Ki67 (>10% pozitiv denotă tumora malignă). De asemenea, dimensiunea tumorii la momentul diagnosticului pozitiv are valoare prognostică prin aceea că o tumoră pînă la 5 cm este probabil benignă, între 5 şi 10 cm are un caracter malign incert, iar peste 10 cm este o tumoră malignă certă.

Comportamentul biologic este etichetat şi de numărul de mitoze (> 5 mitoze/50HPF indică un grad înalt de malignitate).

TABELUL III

Rezultatele marcajului imunhistochimic.

	Localizare	AP uzuală/ Nr mitoze	IMUNOMARCAJ				
			CD 117	CD 34	SMA	S100	Ki67
1 (AM)	ileon	Prolif conj / < 5m / % hpf	+++	++ difuz	++ zonal	+ focal	12–13%
2 (VA)	Jejun + ADK gastric	Prolif conj fasciculata	++ difuz	+ difuz	+ difuz	+ focal	< 1 %
3 (BI)	jejun	Prolif conj fasciculata	++ difuz		+ zonal		2%
4 (MMP)	stomac	Prolif sarc. 30m / 10 hpf	+++	++	+ zonal	-	10 % variabil
5 (LM)	stomac	Prolif conj Rare mitoze	++ difuz	++ difuz	+ focal	+ focal	11-12%
6 (TV)	stomac	Prolif conj	+++ difuz	+ difuz	+ zonal		15%
7 (TF)	sigmoid	Prolif conj	++	+	+/-		2%
8 (SG)	sigmoid	Prolif conj f. rare mitoze	++	+	+		< 1%

Diagnosticul diferențial anatomopatologic a avut în vedere tumorile sistemului nervos autonom gastrointestinal (GANT), leiomioamele, leiomiosarcoamele, schwanoamele, lipoamele, tumorile cu celule granulare.

În total s-au confirmat 11 tumorri stromale maligne şi 13 tumori stromale benigne. Localizarea acestor tumori în tot lungul tubului digestiv este redată în tabelul IV.

Cele mai multe au fost localizate la nivelul stomacului, celelalte localizări fiind în ordine descrescătoare pe jejun, colon stang, ileon şi rect. Un număr de 5 pacienți au fost descoperiți având asocieri de tumori stromale cu alte tumori abdominale: GIST jejunală + adenocarcinom gastric, GIST ileală + chist ovarian bilateral, GIST gastrică + sarcom retroperitoneal, GIST gastrică + hemangiom hepatic, GIST gastrică + chist seros hepatic.

TABELUL IV

Localizările tumorilor stromale: GT(Gastrectomie totala), GST (Gastrectomie subtotala), RC((Rezectie cuneiforma), IH (imunhistochimie); M/B (malign/benign)

	Stomac	**jejun**	**ileon**	**Colon stg**	**rect**
Nr cazuri	15 cazuri	5	1	2	1
M/B	6 / 9	3 / 2	0 / 1	0/2	1 / 0
IH	3	3		2	
Operația	GT 4 GST 7 RC 4	RS 5	RS 1	HC Stg - 1 OH- 1	RAP 1

IH - confirmare prin Imunhistochimie; GT- gastreectomie totala; GST- gastrectomie subtotala; RC- rezectie cuneiforma; RS-rezectie segmentara; HCStg- hemicolectomie stanga; OH- oparatia Hartmann; RAP- rezectie abdominoperineala.

Vîrsta înaintată şi comorbiditațile existente la momentul diagnosticului (diabet, obezitate, litiaza veziculară) au influențat în mod variabil indicația operatorie.

Evoluția postoperatorie a înregistrat complicații la 4 pacienți (17%) din totalul de 24:

- fistula eso-jejunală după gastrectomie totală pentru GIST gastric;
- complicații septice pulmonare la un pacient vîrstnic cu bronhopneumopatie obstructivă cronică, remise sub tratament;
- insuficiență renală acută, reversibilă sub tratament;
- decompensare diabet, reechilibrat prin terapie insulinică.

Nu s-au înregistrat decese la lotul luat în studiu în perioada primelor 60 de zile, până la luarea în evidență în rețeaua oncologică şi începerea terapiei adjuvante.

DISCUȚII

Identificarea celulelor interstițiale Cajal, celule pacemaker ale activității motorii autonome gastrointestinale, ca celule de origine a unei bune părți a tumorilor mezenchimale ale tubului digestiv (aproximativ 80%), a impus în primă instanță rafinarea diagnosticului pozitiv şi diferențial, odată cu statuarea termenului de tumori stromale gastrointestinale (GIST), de către Mazur şi Clark în anul 1983 (7). În fapt, acest grup de tumori, considerate pînă

atunci, în marea lor majoritate, leiomiosarcoame (care, în bună parte, răspundeau la chimioterapie), se dovedeau a fi non-responsive. Imunhistochimia, prin utilizarea anticorpilor monoclonali, este cea care a tranşat diagnosticul, atît pozitiv şi diferenţial, al acestora.

Prezenţa în procentaj ridicat, la nivelul membranelor celulelor Cajal a receptorilor c-Kit (CD 117, SCFR)-85-90% (atît pentru tumorile mici cît şi pentru cele metastazate), a receptorilor CD34 (60-80%), (în 75% din cazuri ei se întîlnesc concomitent la aceeaşi tumora), ca şi, mai rar, a PDGFR (5%), certifică diagnosticul de tumora GIST. În fapt, este vorba de modificări apărute predominant la nivelul porţiunii intracelulare a receptorului c-Kit (consecutive unor mutaţii la nivelul genei c-Kit, situate pe cromozomul 4 la om) . Mai nou, chiar şi pentru tumorile fără răspuns pozitiv la cei doi receptori, un nou receptor a intrat în setul de diagnostic pozitiv: DOG-1 (discovered on GIST-1).

În faţa unei tumori confirmate GIST, o a doua dilema apare: cât de "malignă" este o astfel de tumoră? Există diferenţe între agresivitatea unei tumori gastrice şi a unei tumori intestinale, sau cu altă localizare pe tubul digestiv? Se consideră actual că nici o tumoră GIST nu poate fi considerată, *a priori*, "benignă" (8). Experienţa acumulată în cele două decenii de când se vorbeşte de tumori GIST a permis identificarea câtorva markeri prognostici:

1. *Mărimea* tumorii: astfel, pentru tumorile pînă la 5 cm diametru, riscul de transformare malignă este scăzut (tumori între 2-5 cm), sau foarte scăzut (0-2 cm).

2. *Indexul mitotic*, definit prin numărul de mitoze pe câmpul microscopic de înaltă rezoluţie (HPF), care indică o tumoră cu o proliferare marcată în cazul unui index de peste 5 mitoze/50 cîmpuri studiate. Tot aici putem include şi celulele tumorale al căror procentaj de celule Ki 67 + depăşeşte 70% din numărul total de celule (malignitate înaltă) (9).

3.*Localizarea* tumorii poate orienta asupra potenţialului malign: astfel, se consideră că tumorile gastrice au un prognostic mai bun faţă de cele intestinale.

Într-un amplu studiu pe 1684 pacienţi, Miettinen et al. (10), au corelat primii doi markeri prognostici menţionaţi (mărimea tumorii şi indexul mitotic) cu localizarea acesteia: astfel, ei au arătat că GIST gastrice au un risc crescut (>50%) de evoluţie nefavorabilă (inclusiv progresia bolii sub tratamentul cu Imatinib), atunci cînd dimensiunea tumorii e mai mare de 5 cm, iar indexul mitotic >5/50 HPF, pe cînd tumorile GIST intestinale prezintă acelaşi risc ridicat chiar atunci când dimensiunea tumorii e <2 cm, dar cu indexul mitotic >5/50 HPF. În plus, alte două caracteristici pot orienta către o apreciere a modului de evoluţie a tumorii: astfel, cele cu celularitate crescută şi care se prezintă cu o necroză scăzută, au un potenţial evolutiv mai bun.

Atitudinea terapeutică în cazul unei tumori GIST a cunoscut, în aceste două decenii, un reper calendaristic extrem de important. Astfel, până în anul 2000, intervenţia chirurgicală era considerată prima secvenţă, cea mai importantă, din arsenalul terapeutic adresat pacientului cu tumoră GIST:

- rezecţia completă, „*en bloc*" a tumorii, ori de câte ori acest lucru era posibil, cu evitarea rupturii tumorii.
- evitarea limfadenectomiei (tumorile au tendinţa de a interesa structura parietală în întregime, cu invazia organele învecinate, metastazând rar pe cale limfatică - doar 10% din cazuri;

- peritonectomie largã, atunci când există diseminare peritoneală.

S-a constatat că o rezecție curativă R0 este urmată în 50 % din cazuri de dezvoltarea recidivei locale (de multe ori consecutiva rupturii intraoperatorii a tumorii), sau a metastazei la distanță. Supraviețuirea la 5 ani este cuprinsă între 32 – 78 % (13), iar supraviețuirea la 10 ani variază între 19 – 63 %.

Literatura arată o variabilitate mare a supraviețuirii. Această constatare a intrigat unii autori şi a condus, ulterior, la studiul profilului genetic al pacientului: s-a constatat astfel că receptorul c-kit prezintă diferite modificări în structură, cu sedii diferite, în funcție de mutațiile ce apar la nivelul protooncogenei c-kit. Rapoartele cu privire la polichimioterapia postoperatorie (Doxorubicina, Dacarbazina, Epirubicina, Paclitaxel, s.a.), s-a corelat cu o rată de răspuns parțial (PRR) dezamăgitoare, de doar 8%. În acelaşi timp, radioterapia postoperatorie a fost adresată cazurilor R1- R2, (cu reziduu tumoral), cu rezultate incerte.

O schimbare majoră în tratamentul GIST a constituit-o introducerea, în premieră pentru o tumoră malignă digestivă, a unei terapii țintite la nivelul celulei tumorale. Utilizarea Imatinibului cu varianta sa, Imatinib mesylate, (folosit inițial în tratamentul leucemiilor mieloide cronice), a permis un abord direct al celulei tumorale. Blocarea receptorului tirozin-kinazic c-Kit (CD117, SCFR) de la nivelul membranei celulei Cajal, duce la o blocare a procesului de autofosforilare a acestui receptor, (apărută în condițiile unor mutații la diferite nivele ale protooncogenei c-kit), şi, implicit, la o diminuare a ratei multiplicării celulelor tumorale. În plus, Imatinib blochează şi un alt receptor cu funcție kinazica, Akt1, o serin/treonin kinază. În acest fel, Imatinib creşte semnificativ rata distrugerii celulelor tumorale prin apoptoza. O serie de alte mecanisme care duc la blocarea multiplicării celulelor tumorale după 24-48 ore de la administrarea Imatinib sunt în studiu.

În prezent, se consideră că dacă GIST este rezecabilă şi nu este metastazată (ficat, cel mai des, epiploon sau peritoneu), primul pas rămâne intervenția chirurgicală cu intenție R0. În ultimii ani s-a perfecționat şi abordul laparoscopic al acestora, în special pentru formațiunile mici, fără necroză evidentă (care ar creşte riscul diseminării intraperitoneale) (11, 12). Tratamentul cu Imatinib la aceşti pacienți se începe în adjuvanță pentru o perioadă de 12 luni postoperator, pentru a preveni recidiva. S-a constatat că riscul recidivei este de 6% pentru cei tratați cu Imatinib, față de 17% care nu urmează tratament. Dacă diagnosticul de GIST a fost pus în preoperator, prin certificare imunhistochimica, şi tumora e metastazată sau potențial nerezecabilă, planul terapeutic se modifică, tratamentul începând, de această dată, cu Imatinib. Dacă, sub tratament cu Imatinib boala se stabilizează sau se remite (criterii clinice, biologice, imagistice care atestă dispariția formațiunii) se indică tratamentul chirurgical (13,14). În situațiile în care boala progresează sub tratament, tratamentul chirurgical nu este recomandat.

Rata supravieturirii la pacienții cu tumori stromale nerezecabile sau metastazate, în urma tratamentului cu Imatinib, Sunitinib (17, 18) sau Nilotinib (19, 20) a ajuns de 75-80% la 2 ani (14). Tratamentul chirurgical în cazul formelor avansate, pe lângă îndepărtarea tumorii, are avantatajul de a preveni dezvoltarea rezistenței secundare la tratamentul ulterior cu Imatinib şi, în plus, prelungeşte semnificativ atît intervalul liber de boală, cât şi supraviețuirea

globală (15).

În situația când tumora nu a fost confirmată ca GIST în preoperator şi este local avansată, pretându-se frecvent la confuzia cu un adenocarcinom local avansat, devine obligatorie cel puțin o biopsie prin laparotomie/laparoscopie pentru certificarea diagnosticului şi instituirea tratamentului cu Imatinib (aşa cum a fost cazul cu o parte din cazuistica prezentată).

CONCLUZII

Diagnosticul clinic şi imagistic poate releva unele aspecte ce sugereaza GIST; cu tote acestea, tumorile stromale pot constitui o descoperire surpriză la examenul anatomopatologic microscopic.

Cea mai frecventă localizare este cea gastrică, incidența tumorilor stromale scăzând spre capătul distal al tubului digestiv; de asemenea, stomacul este sediul celei mai frecvente localizari de tumoră stromală malignă.

Abordul chirurgical primar al tumorilor nemetastazate constituie cea mai bună opțiune terapeutică; tehnica chirurgicală impune rezecție largă dar nu şi limfadenectomii extinse ca în cazul carcinoamelor.

Confirmarea GIST prin imunomarcaj este necesară pentru încadrarea fenotipică, definirea agresivității şi aprecierea indicației de terapie adjuvantă.

Diagnosticul imunhistochimic orientează pacientul către un tratament oncologic specific cu anticorpi monoclonali (Imatinib sau Nilotinib) care poate preveni recidiva neoplazică şi îmbunătățeşte prognosticul pacienților.

NOUTĂȚI

NIVEL CRESCUT AL COFEINEI ÎN SÂNGE ASOCIAT CU RISC SCĂZUT AL PROGRESIEI SPRE DEMENȚĂ

Deşi studiile epidemiologice efectuate la om şi animale evidențiază rolul protector al cofeinei împotriva bolii Alzheimer, nu există dovezi directe în acest sens. În studiul efectuat asupra a 124 de persoane (65-88 ani) a fost utilizat drept marker biologic nivelul cofeinei în plasmă, li s-a stabilit nivelul cognitiv şi au fost monitorizați timp de 2-4 ani. Nivelul plasmatic al cofeinei inițial a fost scăzut în deprecierile cognitive medii, respectiv la pacienții ce au progresat către demență (grupul I), comparativ cu nivelul pacienților cu deprecieri cognitive medii stabili (grupul II). Niciunul dintre pacienții grupului I nu a atins nivelul critic al cafeinei de 1200ng/ml, în timp ce jumătate dintre cei din grupul II-lea au prezentat nivele peste 1200 ng/ml. Astfel că nivele peste 1200 ng/ml (≈ 6 μM) sunt considerate a împiedica evoluția spre demență. Dintre 11 citokine determinate plasmatic, doar 3 (FSCG,IL-10,IL-6) au scăzut şi numai la pacienții grupului I. Cafeua a fost singura sursă de cofeină pentru pacienții grupului II. Studiul dovedeşte corelația directă a consumului de cafeină cu riscul scăzut al evoluției spre demență sau întîrzierea acesteia la pacienții care au deprecieri cognitive medii (Chuanhai Cao, David A. Loewenstein, Xiaoyang Lin et al. High Blood Caffeine Levels in MCI Linked to Lack of Progression to Dementia. *Journal of Alzheimer's Disease*, 2012,30(3):550-572).i

IMMUNOTHERAPY IN ADVANCED HEPATOCELLULAR CANCER (Abstract): Hepatocellular carcinoma (HCC) is the commonest primary cancer of the liver, with a poor prognosis in advanced setting. Current treatment for advanced HCC includes mainly sorafenib and more recently approved regorafenib and nivolumab, as chemotherapy has shown little benefit. However, the modest benefit and the low response rate from systemic treatments suggest an increased need for new strategies. Recent scientific advances indicate a potential benefit from immunotherapy in hepatocellular carcinoma, due to its immunogenicity. Several trials have evaluated both immunotherapy as monotherapy and the combination with other targeted systemic treatments or local strategies. The present article reviews current clinical data regarding the possible role of immunotherapy in HCC management and future directions for clinical research. **Keywords**: IMMUNOTHERAPY, HEPATO-CELLULAR CANCER, CLINICAL TRIALS, LIVER.

Hepatocellular carcinoma (HCC) is one of the leading causes of cancer mortality worldwide (1), being the most frequent primary malignancy of the liver. Although 60-80% patients with HCC have liver cirrhosis (2), it can also arise without any underlying disease. Viral infections with B hepatitis, C hepatitis are the most prevalent factors, but other factors such as alcohol, metabolic alterations (hemochromatosis, Wilson disease, α-1 antitrypsin deficiency) non-alcoholic fatty liver disease, genetic and environmental factors have been considered implicated in HCC (3).

Clinical features and diagnosis of primary hepatocellular carcinoma

Patients who develop HHC usually have no symptoms other than those related to their chronic liver disease. Suspicion for HHC should be heightened in patients with previously compensated cirrhosis who develop decompensation such as ascites, encephalopathy, jaundice or variceal bleeding. Hypoglycemia is a well-known paraneoplastic manifestation of hepatocellular carcinoma usually occurring in the terminal stages of the disease. However, during initial presentation this manifestation is uncommon (4). Differential diagnosis of hypoglycemia in hepatocarcinoma can be done primarily with pancreatic insulinomas. Insulinomas are the most common cause of hypoglycemia related to endogenous hyperinsulinism. The episodic nature of the hypoglycemic attack is due to the intermittent secretion of insulin by the tumor (5).

Although loco-regional therapies have provided a benefit for patients diagnosed with early disease, 60% of HCC are diag-

nosed in the advanced setting. Current treatments for advanced HCC include sorafenib in the first line setting, a tyrosine-kinase inhibitor which provide a survival benefit of 2.8 months compared to placebo 10.7 months vs. 7.9 months; hazard ratio in the sorafenib group, 0.69 (95% confidence interval [CI], 0.55 to 0.87; P<0.001) according to the SHARP trial (6).

Regorafenib was recently approved in second line setting, after the RESORCE trial (7) has shown an improved overall survival (HR= 0.63, 95% CI 0·50-0·79; one-sided p<0·0001, median overall survival 10.6 months vs. 7.8 months) compared to placebo in patients progressing to sorafenib.

Food and drug administration (FDA) recently approved nivolumab after progression to sorafenib, based on CheckMate 040 trial (8), a phase I/II open-label, dose escalation and expansion trial (8) that evaluated the efficacy of nivolumab, a fully IgG4 monoclonal antibody targeting PD-1, in first or second-line treatment in patients with advanced HCC with or without hepatitis C or B infection. 262 patients were included in the trial (48 patients in the dose escalation phase and 214 in the dose expansion phase), receiving 3 mg/kg b.w. every 2 weeks in the dose expansion phase. 77% of the patients completed treatment with a manageable safety profile. In terms of response, the 9-month survival rate was 70% and the median survival was 15 months (CI 95% 9.6-20.2 months). Tumor responses were durable, lasting for a median of 17 months. Both patients who were sorafenib naïve or who progressed after sorafenib benefited from nivolumab. PD-L1 expression was also assessed and only 20% of the patients were PD-L1 positive. Tumor responses were seen in 26% of PD-L1 positive patients and in 19% of PD-L1 negative patients.

The Cancer Genome project (9) characterized the main genomic alterations involved in HCC pathogenesis, as well as potential therapeutic targets. The unfavorable prognosis of patients diagnosed with advanced disease or who progress after loco-regional therapies has encouraged the study of various targeted therapies in clinical trial, such as antiangiogenic therapy, c-MET inhibitors, mTOR inhibitors and various multi-kinase inhibitors.

Immunotherapy has shown a prolonged survival in a variety of tumors and settings, such as non-small cell lung cancer, advanced urothelial cancer, metastatic locally advanced melanoma and head and neck squamous cell carcinoma. In HCC, chronic inflammation and liver injury lead to various genetic and epigenetic alterations. As a result, overexpression of oncofetal antigens recognizable by the immune system leads to a potential antitumor immune response. Evidence supports the fact that HCC has a high antigenity (10) and that it also express a high lymphocytic infiltrate (11), suggesting possible benefit from immunotherapy.

Background

Immune checkpoints represent surface glycoproteins expressed on various cell types involved in the immune response, such as B and T cells, dendritic cells, natural killer cells (NK), tumor associated macrophages, monocytes and myeloid-derived suppressor cells (12). Although in physiological condition this process prevents the over-activation of the T cells against pathogens and limit the peripheral damage, in cancer patients this process leads to tumor immune tolerance, as they are responsible for inhibitory signals delivered to T cells or natural killer cells, leading to their inactivation.

Cytotoxic T-lymphocyte protein 4 (CTLA-4) plays an important role in the

activation of CD4+ T cells. Expressed on the activated T cells and on regulatory T cells (Treg), leads to immunosuppression by antagonizing CD28, enhancing Treg activity and interfering with the function of dendritic cells (13). Treg inhibit the immune response by secreting immunosuppressive factors (TGF-β, IL-10) and depleting IL-2.

The activated CD8+ and CD4+ T cells, B cells, NK, Treg, dendritic cells and monocytes express PD-1. Various hematopoietic cells, antigen presenting cells or parenchymal cells express ligands for PD-1 (PD-L1 and PD-L2). Overexpression of these ligands is induced by cytokines, leading upon binding to PD-1 to increased secretion of IL-10 and, consequently, to CD8+ and CD4+ T cell inactivation. One of the reasons cancer cells escape immune surveillance is by expressing these ligands on their surface.

There is a physiological interaction between different cells (Kupffer cells, hepatic stellate cells, immune cells), providing various mechanisms aimed to limit the inflammatory response to constant antigens. This suggests that the liver offers a more immunotolerant microenvironment compared to other organs. Gene expression analysis (9) of these tumors suggests a high expression of the checkpoint genes, such as CTLA-4, PD-1, PD-L1, without any association with viral infection. Moreover, the presence of lymphocytic infiltration was associated with an improved outcome in patients who underwent surgery for HCC (14).

Clinical trials with checkpoint inhibitors in HCC

Current clinical trials exploring the role of checkpoint inhibitors in HCC have shown encouraging results. Tremelimumab, a fully human IgG2 monoclonal antibody that blocks the CTLA-4, is the first agent evaluated in HCC. In a phase II, non-controlled, multicenter study (15), 21 patients with advanced HCC who progressed to previous therapies were enrolled, 42.9% having a Child-Pugh stage B. They received 15 mg/kg b.w. every 90 days, which now is considered a suboptimal dose of the drug. The disease control rate was 76.4%, with a median time to progression of 6.48 months (CI 95% 3.95-9.14 months) and median overall survival of 8.2 months (CI 95% 4.64-21.34 months). The study also assessed the antiviral effect of tremelimumab, observing a decrease in median viral load in most patients, followed for at least 3 months and observed in 75% of the patients with an immune response. In terms of safety the grade 3 adverse effects were rash (65%), elevated ASAT (70%) and diarrhea (30%), however none of the patients received systemic steroids.

A phase I/II trial (16) evaluated the efficacy of an increased dose of tremelimumab (3.5 to 10 mg/kg b.w. every 4 weeks x 6 cycles and then every 3 months) in combination with local therapy (radiofrequency ablation (RFA) or transarterial chemoembolization (TACE). 32 patients with advanced HCC (75% with BCLC stage C) were included in the trial. 75% had viral hepatitis as cause of liver cirrhosis. In 45% of the patients the stable disease lasted longer than 6 months, the median time to progression being 7.4 months (CI 95% 4.7-9.4 months) and overall survival was 12.3 months (CI 95% 9.3-15.4 months). The safety profile showed a reduced incidence of grade 3 side effects like rash (15%), pruritus (9.3%), diarrhea (6.2%) and elevated ASAT (34%). Blood levels of CD4+ and CD8+ T cells increased after tremelimumab administration.

Future directions

The clinical development of checkpoint

inhibitors in HCC shows promising results, considering the disappointing results in drug development for patients with advanced disease in the last decade.

A randomized, phase III trial (NCT 02576509) of nivolumab versus sorafenib is currently ongoing, with the aim to better explore the role of immunotherapy in HCC. The activity of pembrolizumab (NCT 02702401), another PD-1 blocking drug, against supportive care in patients previously treated with sorafenib is currently ongoing. Other ongoing trials are exploring the use of immunotherapy as monotherapy in both first and second-line setting, such as pembrolizumab (NCT 02702414) or nivolumab (NCT 01658878).

Considering the benefit of double blockade in other setting such as melanoma, blocking both PD-L1 and CTLA-4 seems to be an attractive approach. One ongoing trial (NCT 02519348) is comparing durvalumab in combination with tremelimumab *vs.* each agent as monotherapy in first and second-line setting HCC. Moreover, it has been shown that intrahepatic CD8+ T cells in patients with chronic hepatitis C infection seem to be refractory to PD-1/PD-L1 blockade, despite the increased PD-1 expression (17). However, the combined blockade of CTLA-4 and PD-1 seem to overcome this resistance (18) and have efficacy in HCC (15).

TGF-β plays a unique role in the pathogenesis of HCC, as it can act as a tumor suppressor in early stage cancer development. In preclinical models, TGF-β increased the PD-L1 expression in dendritic cells and induces the apoptosis of T cells, increasing the percentage of regulatory T cells (19,20). An ongoing trial (NCT 02423343) is currently exploring the efficacy of combination nivolumab and galunisertib, a TGF-β inhibitor.

Other pathways targeted in combination with immunotherapy in HCC are c-met and VEGF. Ongoing trials with a c-met inhibitor, capmatinib (NCT 02795429) and VEGFR2 inhibitor (NCT 02572687) have been reported.

Due to the already proven benefit of various local therapies for patients in earlier settings and the encouraging data on checkpoint inhibitors, the combination of immunotherapy with local treatment could help patients with HCC. Adding checkpoint inhibitors to TACE or liver ablation seems a feasible combination, as both local treatments seem to increase T cell infiltration (21), especially CD8+ cells. The combination between TACE and tremelimumab (16) has been explored in a small study; more trials are needed to support the suggested data. As radioembolization is increasingly used in HCC and there seem to be a potentially synergistic effect between radiotherapy and CTLA-4 blockade (22), clinical trials are trying to exploit this possibility with nivolumab and Y90 radioembolization (NCT 03033446 and NCT02837029) in HHC patients.

Primary resistance to immunotherapy has been observed in CheckMate 040 study (8), where objective remissions were seen in only 26% of PD-L1 positive patients, suggesting a need for predictive biomarkers and alternatives for these patients. As PD-L1 expression seem to be correlated with various markers of tumor aggressiveness, such as AFP levels, microvascular invasion, poorer histological differentiation (23), more trials that include biomarker evaluation are needed.

CONCLUSIONS

Sorafenib remains the only approved first line treatment in advanced HCC and levantibib is being considered for approval

in first line setting by FDA based on the reported results of REFLECT trial (NCT 01761266). In patients progressing to sorafenib, new drugs such as regorafebib and nivolumab have already been approved. However, there are still unmet needs that must be addressed. The role of combination systemic and local treatment, as well as combined systemic treatment is still unknown.

Immunotherapy is a novel approach in the treatment of advanced HCC, alongside with the development of other agents targeting the main pathways involved in HCC development. Early preclinical and clinical data are encouraging, although further clinical trials exploring monotherapy or combination treatment strategies are needed. There is a need to further define the patients that may benefit most from this approach, as well as its role in combination with other known treatment modalities.

NEWS

THE VETERAN NASAL CANNULA - STILL A CARD UP THE ANAESTHESIOLOGIST'S SLEEVE?

High-flow nasal oxygenation (Hi) has already shown its benefits in awake, sedated or asleep with obstructive sleep apnea spontaneous breathing patients. The use of SponTaneous Respiration using IntraVEnous anaesthesia and Hi (STRIVE Hi) technique, applying a FiO_2 =1 during the induction phase was studied in thirty cases of adult patients who undergone elective laringotracheal surgery, 87% of which with significant airway and/or respiratory compromise. None experienced apnea or complete airway obstruction during induction, with the lowest median oxygen saturation of 100%. If the technique continued during maintenance, the median duration of spontaneous ventilation was of 44 minutes and the median $ETCO_2$ at the end of spontaneous ventilation of 6.8 kPa. Hi's increase in oxygenation, ventilation and upper airway patency are the advantages that help manage difficult airways, while maintaining normoxia (Booth AWG, Vidhani K, P.K. Lee, and Thomsett C-M. SponTaneous Respiration using IntraVEnous anaesthesia and Hi-flow nasal oxygen (STRIVE Hi) maintains oxygenation and airway patency during management of the obstructed airway: an observational study. *British Journal of Anaesthesia*. 2017 Mar; 118(3): 444–451).

AVANTAJELE OPERAȚIILOR TENSION-FREE CU MATERIALE PROSTETICE ÎN CURA HERNIEI INGHINALE

R. Dima
Universitatea Oradea, Facultatea de Medicină şi Farmacie
Facultatea de Medicină
Departamentul de Chirurgie
Spitalul Clinic de Urgențe Oradea

THE BENEFITS OF TENSION-FREE OPERATIONS WITH PROSTHETIC MATERIALS IN THE REPAIR OF INGUINAL HERNIA (Abstract): Recurrences after inguinal hernia repair represent a significant problem for both surgeons and patients. **Material and methods**. This study tries to evaluate operations that were performed in Clinical Emergency Hospital Oradea, II-nd Surgical Department, between September 2007 and December 2009, using polypropylene meshes. The operations were performed using the Lichtenstein technique in loco-regional or general anesthesia. The follow up was performed at one month after surgery and then at 3, 6, 12 months with a compliance rate of 80%. **Results.** were similar to the results found in literature. **Conclusions**. The technique is easy to learn and to perform and the benefits for patients are represented by the low recurrence rates, comfort due to low levels of postoperative pain, early discharge and early socio-professional reintegration. **Key words**: INGUINAL HERNIA, LICHTENSTEIN OPERATION, RECURENCE

Recurențele după repararea herniei inghinale reprezintă o problemă de larg interes pentru chirurg şi pacient (1). Evidențele arată că există o perturbare a metabolismului implicată în patogeneza herniei inghinale la adult care determină modificări în funcțiile dependente de *fascia transversalis*. Rezultă că utilizarea unui astfel de țesut cu rezistența scazută este problematică în reparația herniei inghinale (2). Într-o încercare de a reduce incidența recurenței şi de a întări reconstrucția plastică au fost utilizate variate tehnici cu țesut autolog sau biomateriale. În urmă cu peste un secol Usher (cit. 1) a propus utilizarea polietilenei cu densitate mare pentru repararea defectelor tisulare la nivelul toracelui şi peretelui abdominal. De atunci s-a observat o tendință spre o largă utilizare a materialelor sintetice (3).

MATERIAL ŞI METODE

Studiul de față îşi propune o evaluare a intervențiilor chirurgicale în care s-au utilizat plase de polipropilenă în Clinica Chirurgie II a Spitalului clinic de Urgență din Oradea, în perioada Septembrie 2007 – Decembrie 2009. S-au efectuat 73 de intervenții chirurgicale folosind tehnica Lichtenstein (4) din care 26 au fost indicate pentru cura bilaterală. Hernia inghinală a fost indirectă în 47 de cazuri, directă în 15 şi mixtă în 11. Vârsta pacienților, toți de sex masculin, a fost cuprinsă între 18 şi 79 cu o medie de 52,3 ani, toți pacienții fiind de sex masculin (tab. I, fig. 1). Operațiile s-au efectuat în anestezie loco-regională sau generală.

TABELUL I

Distribuția pe grupuri de vârstă a pacienților incluşi in studiu

Vârsta (ani)	Nr.	% *
<30	1	1,4
31-40	8	11,0
41-50	19	26,0
51-60	27	37,0
61-70	15	20,5
>70	3	4,1

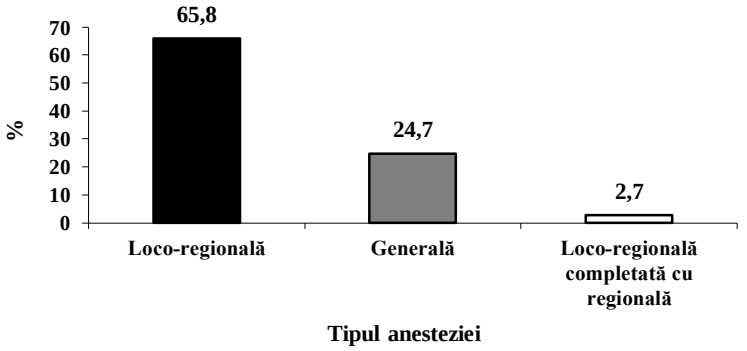

Fig. 4. Repartiția pacienților în relație cu tipul de anestezic folosit la tratamentul chirurgical

Tehnica operatorie. Intervențiile chirurgicale s-au realizat sub anestezie locoregională sau generală (tab. IV, fig. 4), pacientul aflat în clinostatism, cu regiunea inghinală pregătită, iar înainte de incizie s-a administrat, intravenos, o doză de cefalosporină de generația a IIa. După incizia pielii, țesutului subcutanat şi a aponevrozei muşchiului oblic extern cordonul spermatic s-a ridicat de pe peretele posterior al canalului inghinal şi s-a evidențiat traiectul nervilor ilio-hipogastric, ilio-inghinal şi genital.

În herniile indirecte sacul herniar a fost identificat, disecat de inelul profund şi deschis pentru a permite examinarea conținutului, sacul herniar ligaturat la bază cu rezecția porțiunii distale.

Plasa de polipropilenă a fost ajustată pentru a se potrivi dimensiunilor canalului inghinal urmată de fixarea la vârf de tuberculul pubic. Apoi s-a suturat cu fire separate marginea inferioară a plasei la ligamentul inghinal după practicarea unei deschideri prin marginea inferioară a plasei pentru acomodarea funiculului spermatic până la nivelul crestei iliace anterioare. De asemenea, sunt suturate cele două margini rezultate prin tăierea plasei în jurul cordonului spermatic. Colțul infero-medial al plasei a fost suturat astfel încât să acopere tuberculul pubic, iar medial plasa a fost suturată la tendonul conjunct şi s-a practicat controlul hemostazei. În cazul unor hernii voluminoase s-a plasat un tub de dren sub aponevroza oblicului extern suturată cu fire separate şi, în final, s-a închis plaga chirurgicală (5) (fig.5)

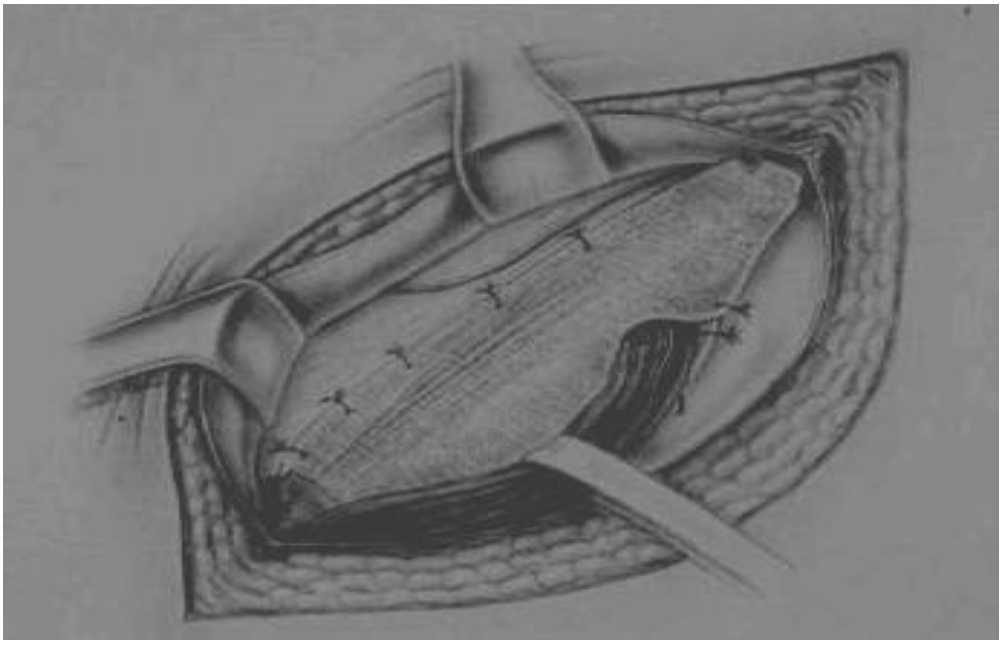

Fig. 5. Poziționarea plasei pe peretele posterior al canalului inghinal

Postoperator au fost administrate antibiotice pe durata a aproximativ 48-72 de ore. De asemenea, la pacienții cu risc crescut s-a administrat heparină cu greutate

moleculară mică pentru prevenția trombozei venoase profunde, cu 12 ore preoperator şi postoperator, pe toată durata spitalizării (6). Analgezia postoperatorie a fost asigurată prin administrarea de antialgice minore. Durata medie de spitalizare a fost de 3 zile.

REZULTATE

Durerea postoperatorie a fost controlată cu ajutorul analgezicelor minore (7). În perioada imediat postoperatorie s-au înregistrat complicații; 2 hematoame, 3 seroame (morbiditate = 6,84%) şi 3 cazuri cu edem testicular care a cedt la administrarea de AINS şi drenaj postural. Nu s-au semnalat abcese sau infecții (tab. V, fig. 6, 7).

Urmărirea pacienților a fost efectuată la 1, 3, 6 şi 12 luni de la externare cu o complianță de 59 de pacienți (80%), prin examinare clinică. Nu s-a înregistrat nici o recidivă herniară.

Nevralgia severă nu s-a înregistrat la nici un caz (8), dar în 5 a fost prezentă durerea postoperatorie pe o durată de peste 2 săptămâni, care a cedat, progresiv, sub administrare de antiinflamatoare nesteroidiene (9).

DISCUȚII

Descrierea tehnicii Lichtenstein fără tensiune, în urmă cu peste doua decenii, a deschis o nouă eră în chirurgia herniară. Metoda este simplă, eficientă, durerea postoperatorie este minimă datorită lipsei de tensiune iar rata de recurență este extrem de joasă(variază între 0 şi 2% în literatură) operația poate fi efectuată sub anestezie locală sau loco-regională. Din aceste motive această tehnică este cea mai preferată pentru reconstrucția plastică a canalului inghinal (10).

În prezent, chirurgii beneficiază de existența unei largi varietați de plase având calitatea de a fi inerte, rezistente la infecție, cu permeabilitate moleculară, pliabilitate, transparență, integritate mecanică şi biocompatibilitate. În schimb plasele absorbabile nu se mențin suficient timp pentru ca depozitele de colagen să fie adecvate iar cele multifilament predispun la infecții. Plasele monofilament sunt cele mai solicitate, fiind prezentate în variate tipuri de polipropilenă. Utilizarea plaselor poroase determină o suprafață largă de creştere în porii plasei a țesutului de conectivitate pemițând o fixare permanentă a protezei în peretele abdominal. Poziționarea intraparietală a plasei permite integrarea într-un țesut bine vascularizat şi o bună acoperire. Temerile legate de implantarea plasei s-au dovedit nefondate. Drenajul aspirativ s-a dovedit util în cazul herniilor inghinale mari pentru a minimaliza formarea hematoamelor şi a seroamelor. Durata menținerii drenajului şi a utilizării prevenției cu antibiotice este evaluată în mod diferit (11, 12).

Pentru a reduce incidența recidivei herniare plasa trebuie să depăşească cu 2-4 cm. marginile triunghiului Hesselbach. Poziționarea plasei sub aponevroza muşchiului oblic extern este necesară deoarece presiunea intraabdominală acționează în favoarea reparației, aponevroza muşchiului oblic extern fixează plasa în poziție acționând ca un suport extern când presiunea intraabdominală creşte. Plasa trebuie fixată cu atenție pentru a preveni plicaturarea,

şifonarea sau răsucirea acesteia în jurul cordonului spermatic.

Metoda poate fi aplicată şi de chirurgii care nu practică frecvent chirurgia herniară şi este eficientă în prevenţia recidivei care nu depăşeşte 0 – 2%. De asemenea, metoda prezintă o bună evoluţie postoperatorie, cu un control accesibil al durerii şi reintegrare socio-ocupaţională rapidă.

CONCLUZII

Metoda Lichtenstein este accesibilă, cu posibilitatea de a fi aplicată şi de chirurgii care nu prezintă un interes deosebit faţă de chirurgia herniară.

Tehnica nu a fost grevată de complicaţii majore, iar materialul prostetic utilizat nu a favorizat apariţia infecţiei postoperatorii sau a recidivei herniare.

Evoluţia postoperatorie a fost confortabilă cu un control al durerii uşor de aplicat, durată de spitalizare redusă, reintegrarea socio-ocupaţională realizată pe termen scurt.

STATISTICAL DATA CONCERNING HEAD TRAUMA WITH FRONTAL SINUS INVOLVEMENT IN CLINICAL HOSPITAL "PROF. DR. NICOLAE OBLU", IASI (Abstract): We present here some interesting points of view concerning head and brain injury with frontal sinus involvement. **Material and methods:** In general neurosurgical practice the frontal sinus traumatic involvement is about 3-5 per cent from all head trauma; we proposed to realise a extensive 5 years study to finnaly sumarise the characteristical elements for our geographical area. The amount of patients hospitalized in our clinic was about 80 000 in five years. **Results:** Concerning our statistical data, there are 677 patients with frontal sinus injury, 490 from this were complicated with brain pathology. **Conclusions:** We concluded there are differences between our series and the other studies from developed countries, in our region the domestical (agricultural works) causes are about 10% higher. **Key words:** FRONTAL SINUS, SKULL FRACTURE, HEAD TRAUMA

MATERIAL ŞI METODE

Studiul a inclus 80891 pacienti asistați în perioada 2002-2007 în Clinicile de Neurochirurgie ale Spitalului Clinic de Urgență „Prof. Dr. Nicolae Oblu" din Iaşi. Din totalul pacienților, 3658 (4%) prezentau leziuni considerate a fi corelate cu etajul anterior al bazei craniului. Leziunile la nivelul fosei craniene anterioare au fost decelate la 1295 pacienți (1,6%). Aşadar ne referim la un segment foarte strâns cazuistic, aspect întâlnit şi în literatura de specialitate internațională (1).

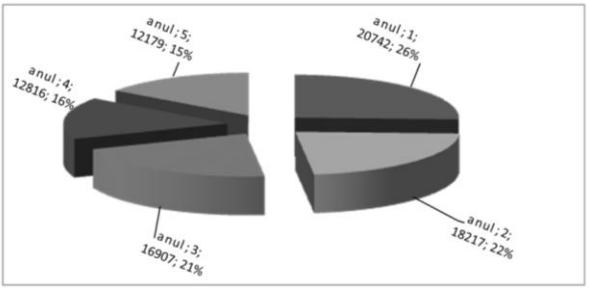

Fig. 1. Distribuția cazurilor incluse in studiu in 2002-2007

Toți pacienții au fost evaluați preoperator prin examen CT (prin secțiuni axiale şi coronale). Reconstrucția coronală a fost utilizată doar la pacienții ce nu se puteau poziționa adecvat scanării coronale. Parametrii utilizați pentru clasificarea pacienților au fost: vârstă, sex, etiologie, loc al traumei, prezența fracturilor cranio-faciale, a leziunilor asociate şi prezența complicațiilor, aceste criterii fiind cel mai des urmărite în majoritatea studiilor similare (2).

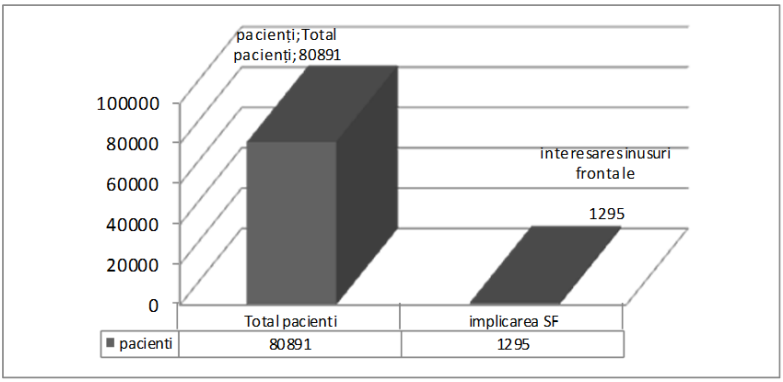

Fig. 2. Situația pacienților cu leziuni ce implică sinusurile frontale

În studiu s-au luat în considerație următoarele tipuri de leziuni:

- congenitale – 16;
- traumatice - 677;
- inflamatorii - 127;
- neoplazice cu origine la acest nivel sau prin extensie de vecinătate - 353;
- vasculare – 122.

Pe elemente de categorie lezională predomină traumatismele cranio-cerebrale, apoi patologia inflamatorie, tumorală şi leziunile vasculare şi congenitale.

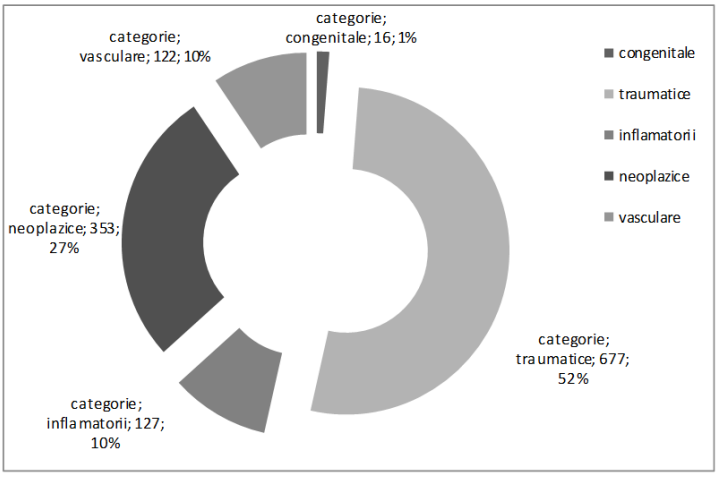

Fig. 3. Grupuri patologice studiate

Pacienții au fost evaluati pe grupuri de vârstă, tipuri de leziune, mediu de proveniență modul de rezolvare (chirurgical/conservator).

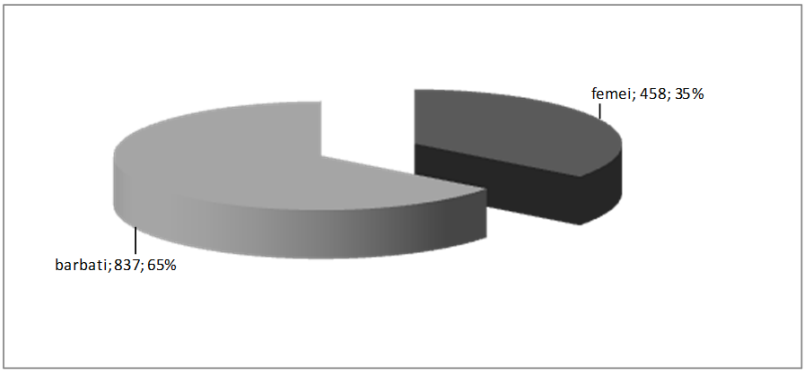

Fig. 4. Repartiția pe sex a pacienților cu leziuni ce interesează etajul anterior al bazei craniului

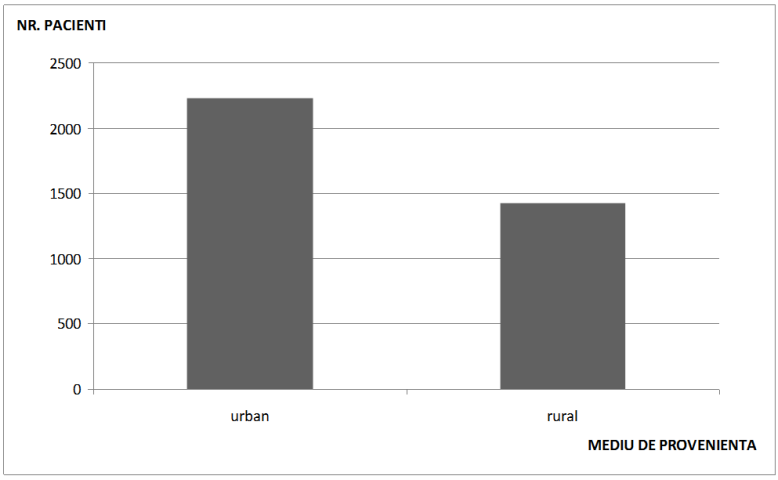

Fig. 5. Distribuția pe mediu de proveniență

REZULTATE

Pe grupuri de mediu rural/urban au predominat elementele patologice corelate cu accidentele de trafic rutier, dar corelate, de asemenea, şi cu o rată de diagnosticare mai ridicată, datorită creşterii numărului de centre specializate în politraumă la nivelul oraşelor. Din datele analizate reiese că implicarea sinusurilor aerice frontale apare în 677 (52,3%) din traumatismele cerebrale luate în studiu, iar din acestea 490 (72,4%) sunt expuse diverselor complicații; majoritatea dintre acestea au apărut în perioada acută, fapt concordant şi cu alte studii din literatura de specialitate (2).

Cea mai mare incidență se remarcă la nivelul grupelor de vârstă active, între 20-50 de ani; incidența este foarte redusă sub vârsta de 20ani datorită, pneumatizării limitate.

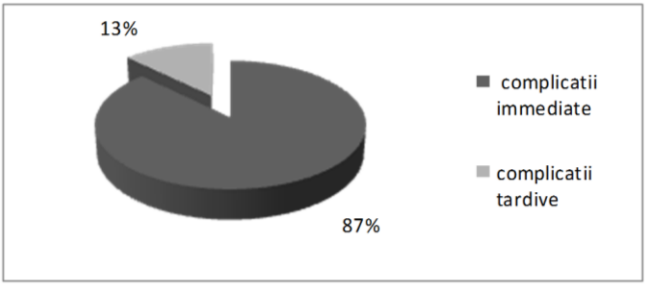

Fig. 6. Pacienți cu interesare traumatică la nivelul sinusului aeric frontal

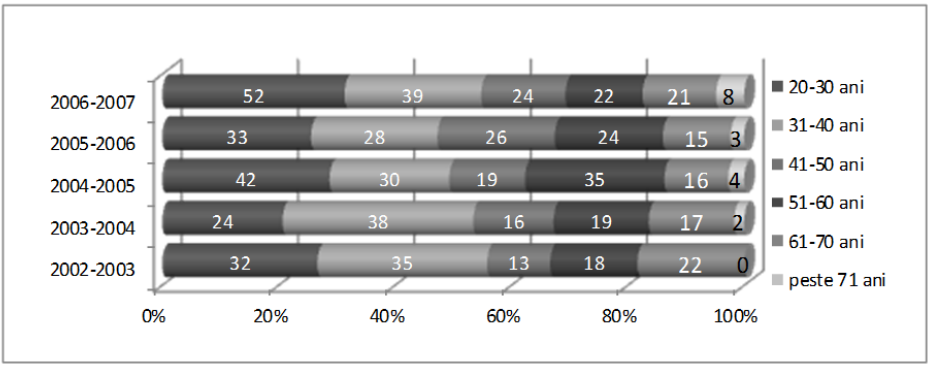

Fig. 7. Repartiția cazurilor pe ani de studiu şi intervale de vârstă

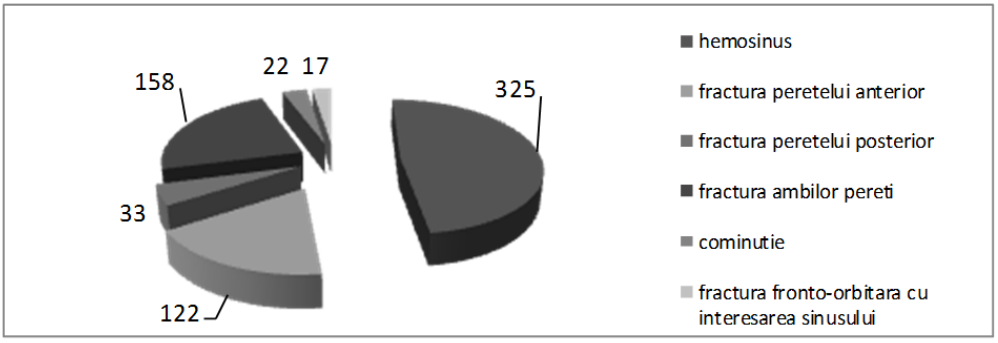

Fig. 8. Tipuri de interesări traumatice ale sinusurilor aerice frontale

Cea mai comună leziune este hemosinusul frontal (de multe ori asociat cu pan hemosinus), fiind urmată de fracturile pereților sinusurilor aerice frontale.

Din patologia craniocerebrală studiată, aproximativ 4% a fost cu implicarea etajului anterior al bazei craniului şi aproximativ 1,5% reprezintă interesarea fosei craniene anterioare, din care patologia majoritară este cea traumatică, cu preponderență masculină pentru ambele medii de proveniență (3). Evoluția pe luni în frecvența de producere a leziunilor traumatice ale sinusurilor frontale şi în general a traumatismelor craniocerebra-

le a evidențiat incidența scăzută în martie (2,8%) şi aprilie (2,5%). Începând cu luna iunie are loc o creştere aproape constantă a frecvenței de apariție a incidentelor traumatice cranio-cerebrale, până la un maximum atins în luna iulie (17,2%). După o uşoară scădere în luna august (9.9%) se înregistrează o ascensiune în lunile septembrie şi octombrie (corespunzătoare intensificării activităților agricole), după care s-a diminuat accentuat în octombrie, urmată de o creştere în lunile de iarnă.

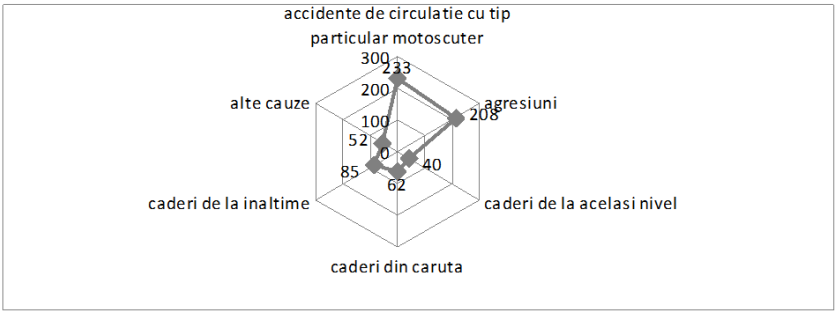

Fig. 10. Repartiția cazurilor pe tipuri etiologice

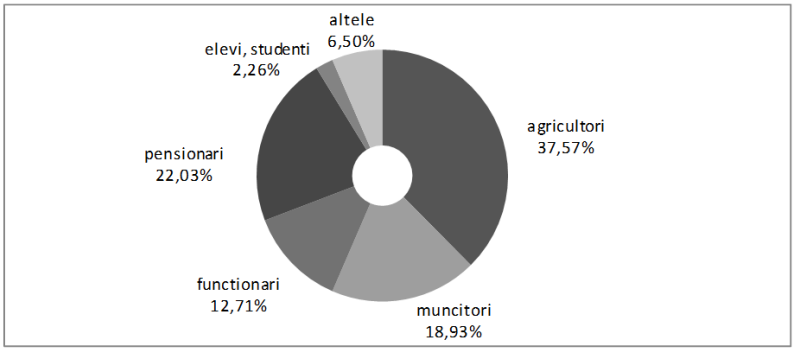

Fig. 11. Distributia cazurilor în relație cu situația ocupațională

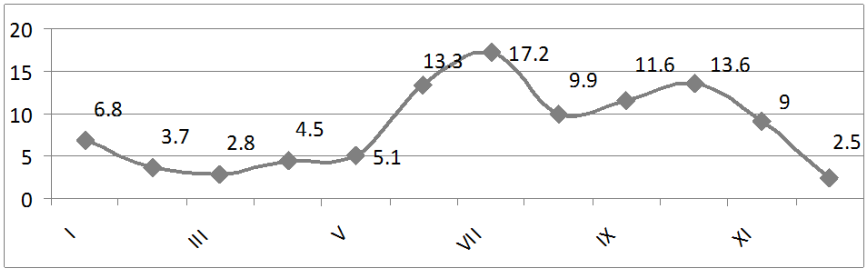

Fig. 12. Distribuția medie lunară a cazurilor cu implicarea traumatică a sinusurilor frontale

DISCUȚII

Analiza statistica a datelor arată o tendință uşoară de creştere a traumatismelor cranio-faciale cu implicare sinusală datorită creşterii numărului de autovehicule, mai ales a motoscuterelor, la care impactul ex-

tremității cefalice este foarte violent (4). Sexul masculin este interesat în proporție de peste 65 % iar ca mediu predomină mediul urban. În ceea ce privește ocupația, sunt interesate toate categoriile, dar mai frecvent muncitorii si agricultorii; mecanismele de producere principale sunt accidentele de trafic şi agresiunile, urmate de căderi accidentale pe fond de etilism. Studiindu-se traumatologia cranio-facială, s-a concluzionat că forța de impact necesar producerii unei fracturi sinusale este între 360-990 kg, ceea ce este suficient pentru a produce şi alte injurii craniene (5). În funcție de intensitatea forței, pot fi injurii ale tăbliilor, anterioară sau posterioară, ultima asociind frecvent şi injurii cerebrale, orbitare sau ale celulelor etmoidale: Wright şi col. au raportat că 76% din pacienții cu injurii ale pereților sinusali au avut alterări ale stării de conştiență şi 93 % au avut multiple fracturi faciale şi craniale (5).

De menționat, în ceea ce privește statistica noastră, ar fi că în comparație cu alte studii realizate în țări cu nivel de dezvoltare mai avansat, apar diferențe semnificative, în regiunea noastră accidentele domestice (în special cele referitoare la lucrările agricole sezoniere) sunt ca procent cu aproximativ 10% mai ridicate (6).

CONCLUZII

Sinusul frontal este o structură deosebit de variabilă în funcție de vârstă, sex, distribuție geografică. Importanța sa în dinamica extremității cefalice, fonație, apărarea antimicrobiană este dovedită. Deşi, în termeni fizici vorbind, structura piramidală a pereților săi îi conferă o elasticitate şi o rezistență deosebite, expunerea anterioară fac din sinusurile frontale o barieră de apărare eficientă. Abordarea statistică a problemelor de neurotraumatologie capătă o importanță deosebită, atât din punct de vedere clinic pentru stabilirea unor protocoale de explorare şi tratament, cât şi din punct de vedere economic, deoarece în problemele de traumă metodele de explorare în vederea tratamentului precoce sunt eficientizate (7).

THE PROGNOSIS OF POSTERIOR URETHRAL VALVES, ASSOCIATED TO VESICOURETERAL REFLUX IN CHILDREN

Aurelia Masca[1], L. L. Indrei[2], Klara Brânzaniuc[3]
1. Sighişoara County Hospital, Department of Pediatrics
2. "Gr. T. Popa" University of Medicine and Pharmacy, Iasi,
3. University of Medicine and Pharmacy, Tg. Mures, Department of Anatomy

THE PROGNOSIS OF POSTERIOR URETHRAL VALVES ASSOCIATED TO VESICO-URETERAL REFLUX IN CHILDREN (Abstract): Posterior urethral valves represent a congenital barrier at the level of the posterior urethra, which opposes miction. They are located near the prostatic urethra, originating at the *verumontanum* level, affecting male patients. The ureters are inconstantly dilated; vesicoureteral reflux is met in 2/3 of the cases. The reflux can be secondary to the sub-bladder barrier, but it can also be considered primitive, determined by the intra bladder ectopy of the ureter. The presence of the reflux is interpreted as a severe associated factor. Semiology is rather unusual, positive diagnosis is based on early discovery or antenatally of the impairment, by fetal echography starting from the 28th week of pregnancy, postnatal echography followed by miction cystography, retrograde urethrography and creatinine dosage complete the diagnosis. The treatment is surgical: endoscopic ablation of the valves (in the absence of renal failure), percutaneous pyelostomy, high lateral ureterostomy, and in severe cases vesicostomy and renal transplant. Prognosis depends on how early the impairment is detected, on the degree of pulmonary hypoplasia, on the presence of the vesicoureteral reflux and the possibility of recovering renal function; 1/3 of the newborns develop in time Chronic Renal Failure which requires renal transplant. The studied group comprised male children diagnosed with vesicoureteral reflux their ages ranking between 0 -18 years, admitted to the Pediatric Clinic, Tg. Mures during the last 10 years and children diagnosed and operated with posterior urethra valves at the Surgical Clinic of the "*M. S. Curie"* Hospital, Bucharest during the last 20 years. Our results show that out of the total number of studied children 25 presented posterior urethra valves and 9 children presented vesicoureteral reflux. We can conclude that the presence of the vesicoureteral reflux is an unfavorable prognosis regarding the degree of renal failure. **Key words**: ANTENATAL ECHOGRAPHY, URETHRAL VALVE ABLATION, PROGNOSIS.

Posterior urethral valves (PUV) represent a congenital barrier at the level of the posterior urethra which opposes miction. These are the most frequent obstructive congenital urethral lesions and affect only male patients, being located in the distal section of the prostatic urethra (1). The incidence of posterior urethral valves is estimated to be 1: 5.000-8.000 (2).

The obstruction determines dilation of the prostatic urethra upstream, hypertrophy of the bladder detrusor muscle, which obstructs the urethrobladder junction.

The vesicoureteral reflux (VUR) is met in 2/3 of the cases, half of these being bilateral. The reflux can be secondary to the

sub-bladder barrier, but it can also be considered primitive, determined by the intrabladder ectopy of the ureter. The presence of the reflux is interpreted as a severe associated factor (3).

It presents an unusual symptomatology: unremitting fever, haematuria, sepsis, dehydration syndrome, urinary infections, dysuria, reduction of urinary jet, urinary incontinence, vesical globus, ureterohydronephrosis, renal failure (4).

Positive diagnosis is established by considering two aspects: antenatal diagnosis and postnatal diagnosis.

Antenatal diagnosis is based on detection of the disease by fetal echography starting from the 28th week of pregnancy, when only a high echo sound can be distinguished: uretero-hydronephrosis (5).

The postnatal diagnosis is based on the echographical examination during the neonatal or infant age, which highlights bilateral hydronephrosis with narrowing of the parenchyma, associated with renal dysplasia and megaureter due to uni- or bilateral reflux, relaxed urinary bladder with thick wall and dilated prostatic urethra (6, 7).

Miction cystography, retrograde urethrography, dosing seric creatinine completes the diagnosis (8, 9) and are considered to be the most important means of diagnosis.

Treatment is surgical intervention: endoscopic ablation of the valves in the absence of chronic renal failure, percutaneous pyelostomy, high lateral ureterostomy, and in severe cases vesicostomy (10) renal transplant (11, 12, 13). Early and correct treatment will avoid renal failure; can stop growth problems and the impairment of sexual function and fertility.

The prognosis depends on how early the impairment is detected, when VUR or chronic renal failure (CRF) are present, which is present in 1/3 of cases (14).

The main purpose of this article is to analyze the degree of the renal function impairment in case of vesicoureteral reflux associated or determined by PUV.

MATERIAL AND METHODS

Studied group: children diagnosed with vesicoureteral reflux between the ages of 0-18 years, of male sex, admitted in the Pediatric Clinic in Tg. Mures during the last 10 years.

Children diagnosed and operated with posterior urethra valves in the Surgical Clinic of the "*M. S. Curie"* Hospital from Bucharest in the last 20 years.

Data has been collected by analyzing medical records of children diagnosed with ureterohydronephrosis, vesicoureteral reflux and posterior urethral valves at the Department of Nephrology, II Pediatric Clinic Tg. Mures and in collaboration with Surgical Clinic from "*M. S. Curie"* Hospital from Bucharest.

Criteria for inclusion: children aged between 0 -18 years; certainty diagnosis of VUR and PUV

Criteria for exclusion:

- children aged between 0 -18 years with medical history of renal impairment
- errors in urodynamic studies
- children aged between 0 -18 years with sepsis, acute dehydration syndrome, unremitting fever having an etiology different from the renal one

Target population: 170 patients with VUR and possible PUV diagnosed at the II Pediatric Clinic in Tg. Mures and 20 children operated on at the Department of General Surgery, "*M. S. Curie"* Hospital, Bucharest.

Available population: investigations began with all those children who presented VUR, uretero-hydronephrosis discovered ante- and postnatally, associated or determined by posterior urethral valves.

Type of study: transversal, analytical, experimental.

Used methods were retrospective study, serial cases, statistical method (descriptive statistics).

Since no pictures were used which could lead to the identification of a patient, there is no informed consent.

RESULTS

This study presents the cases of five children out of 170 children presenting vesicoureteral reflux, were diagnosed with posterior urethral valve, and the cases of 20 children with PUV operated at the surgical clinic M. S. Curie Hospital from Bucharest.

Case number 1

3 years old child diagnosed with: Bilateral ureterohydrone, Operated posterior urethral valve, Relapsing high type urinary tract infection, Deficient anemia.

Discovered postnatally at the age of 4 months.

Treatment: ablation of the valves when he was 5 months old.

Evolution: favorable with repeated urinary infections and deficient anemia.

Case number 2

One year and 4 months old child diagnosed with bilateral ureterohydronephrosis: 1st degree left vesico-ureteral reflux, Posterior urethral valve, Deficient anemia. Diagnosed antenatally by fetal echography at 30 weeks highlighted bilateral hydronephrosis, then exploratory cystography highlighted urethral stenosis, posterior urethral valve and left vesicoureteral reflux.

Treatment: percutaneous cystostomy then valve ablation. Evolution: favorable

Case number 3

9 years old child diagnosed with: 5 degree ureterohydronephrosis by sub-bladder barrier, Posterior urethral valve, 5 degree right vesicoureteral reflux, Chronic renal failure, Bilateral cutaneous ureterostomy, Repeated urinary tract infections. Detected antenatally at 32 weeks of pregnancy, fetal echography visualising bilateral uretero-hydronephrosis

Treatment: bilateral cutaneous ureterostomy, then bilateral ureteral reimplantation and valve resection. Evolution: with 5th degree vesicoureteral reflux and chronic renal failure presently with peritoneal dialysis.

Case number 4

3 years old child diagnosed with: bilateral megadolicoureter, 5th degree bilateral vesicoureteral reflux, Posterior urethral valve, 3rd degree chronic renal failure, Bilateral cutaneous ureterostomy.

Detected postnatally at 5 weeks beginning with signs of 3rd degree acute dehydration syndrome (ADS), urinary tract infection, echography highlighted renal dysplasia; cystography and urography highlighted massive bilateral vesicoureteral reflux.

Treatment: bilateral ureterostomy at age of 10 months.

Evolution: unfavorable with 3rd degree chronic renal failure and peritoneal dialysis.

Case number 5

One year and 5 months old child diagnosed with: Posterior urethral valve,

Congenital hydronephrosis, Megaureter, Prolonged neonatal jaundice, Ostium secundum type atrial septal defect. Immediately detected perinatally with hydronephrosis and megaureter.

Treatment: fitted with a catheter at the Pediatric Clinic without results, programmed endoscopic resection of valves.

Case number 6

22 years child diagnosed with: Chronic urinal retention, PUV, Secondary bilateral uretero-hydronephrosis.

Child hospitalized in 1991 when underwent: Bladder Neck Plasy (Young), cystostomy (Pezzer), Foley *a demeure*, bladder drainage. Rehospitalized in 1992 and underwent surgery at the age of 2 and 3 with valve resection. Evolution: with repeated urinary infection.

Case number 7

11 years old child diagnosed with: PUV, VUR with bilateral hyronephrosis, Hypospadiasis, Micropenis with bifid gland. Detected postnatally, hospitalized at age of 9 months for bifid gland and urethra with hypospadias: it was not operated.

Case number 8

9 years old child diagnosed with: PUV, Bilateral ureterohydronephrosis, urinary tract infection.

Detected perinatally at one month after Foley probe, then at age of 2 month when 5th degree VUR, when undergoing endoscopic resection of valves appears, followed in time II after appreciatively 20 days by terminal cutaneous ureterostomy. Evolution: favorable.

Case number 9

10 years old child diagnosed with: PUV, Bilateral ureterohydronephrosis.

Detected at 10 months subsequently undergoing surgery by endoscopic resection of valves.

Case number 10

22 years old child diagnosed with: PUV, Bilateral ureterohyronephrosis, Bilateral VUR.

Detected postnatally, initially tried to mount a Foley probe, then rehospitalized in 1990 at the age of 2, subsequently undergoing transpubian resection of the valves, after 8 months presenting a chronic fistulizing orchiepididimitis, subsequently undergoing orchidectomy. At age of 5 years old he presented a chronic fistula at the left hemiscrotum and at the age of 12 years old he developed a chronic renal failure, needing peritoneal dialysis.

Case number 11

18 years old child diagnosed with: PUV subsequently undergoing surgery, Bilateral VUR.

Rehospitalized and tide correction in 1999, control after 5 year. Evolution: favorable.

Case number 12

10 years old child diagnosed with PUV. Detected in infant age, surgery at infant age.

Treatment: endoscopic resection of valves, control after 2 years. Evolution: favorable.

Case number 13

10 years old diagnosed with: PUV, Bilateral ureterohydronephrosis.

Detected by echography immediately after birth, at the age of 8 days old subsequently undergoing endoscopic resection of valves. Evolution: favorable.

Case number 14

9 years old child diagnosed with: PUV, Bilateral ureterohyronephrosis, right VUR, left juxta-vesical stenosis. Detected postnatally, hospitalized at age of 2 years old, and subsequently undergoing bilateral ureterostomy.

Case number 15

7 years old child diagnosed with: PUV, Bilateral ureterohydronephrosis, and urinary tract infection.

The disease was detected by echography after birth, hospitalized at the age of 9 months old subsequently undergoing an incision of valves "cold knifes", Foley probe *a demeure*, and then rehospitalized after 2 month subsequently undergoing endoscopic resection of valves.

Evolution: with repeated urinary infections.

Case number 16

7 years old child diagnosed with: PUV, Bladder diverticulum.

Detected after birth, surgery at the age of 2 years and a half, subsequently undergoing endoscopic resection of valves, and after 2 years iterative resection. Evolution with urinary infections and deficient anemia.

Case number 17

4 years old child diagnosed with: PUV type III, Bilateral ureterohydronephrosis, right VUR

Detected antenatally, hospitalized at the age of 3 months subsequently undergoing right ureterostomy, control after 4 months. Evolution: favorable.

Case number 18

6 years old child diagnosed with PUV type III, Bilateral uretherohydronephrosis, hypospadias and meatum stenosis. Ureterohydronephrosis detected postnatally by echography, besides hypospadisis detected at birth. Subsequently undergoing meatoplasty.

Case number 19

9 years old child diagnosed with: PUV type I, Bilateral ureterohydronephrosis.

Hospitalized at the age of 3, subsequently undergoing endoscopic resection of valves, after one year undergoing Bolmers iterative resection.

Case number 20

6 years old child diagnosed with: PUV type I, Bilateral ureterohydronephrosis, Bilateral ureterostomia. Hydronephrosis was revealed antenatally by a fetal echography.

Treatment: bilateral ureterostomya, then at the age of 2 rehospitalized subsequently undergoing initial endoscopic resection of valves and after a month iterative resection of valves.

Case number 21

10 years old child diagnosed with: PUV type I.

Detected postnatally, hospitalized in the surgical clinic at the age of 7 years old for weak urinary stream; subsequently undergoing endoscopic resection of valves.

Case number 22

5 years old child diagnosed with: PUV type I, Bilateral ureterohydrophenosis.

Detected antenatally when fetal echography revealed hydronephrosis, hospitalized at the age of one month, when subsequently undergoing partial endoscopic resection of valves, after 2 months endo-

scopic resection of valves. Evolution: favorable.

Case number 23

5 years old child diagnosed with: PUV type I, Bilateral ureterohydrophenosis, Pyelonephritis.

Diseases detected antenatally by fetal echography, when hospitalized at the age of 12 days, subsequently undergoing surgery by percutaneous cystostomy. Treatment continued at the age of 11 years old when it was practiced vesicostomy. At age of 1 and 2 years old the child underwent endoscopic resection of valves and after a month iterative resection, at the age of 1 and 4 years old endoscopic resection of diaphragm, at the age of 1 and 8 years old finally undergoing vesicostome.

Case number 24

23 years old child diagnosed with: PUV, Bilateral ureterohydronephrosis, Left ureterostomia, left VUR.Rehospitalized at the age of 2 years old, subsequently undergoing left Leadbetter-Poliano reimplantation after which appeared left VUR and at the age of 4 presented left cord cyst for which the child underwent cyst cure. There are no further details about the child's condition after becoming an adult.

Case number 25

22 years old child diagnosed with: PUV, Bilateral ureterohydronephrosis, Bilateral VUR, urinary tract infection. Detected postnatally, subsequently undergoing surgery: peritoneal ureterostomia and also cystostomy at the age of 6 months. Treatment was followed by transpubian, transvesical resection at the age of one year old. It was rehospitalized at the age of 8 years old with urinary incontinence subsequently undergoing right orchidopexy and control after 2 years. There are no further details about the child's condition after becoming an adult.

DISCUSSION

The 25 studied cases coming from the above mentioned two clinics, one of them with a surgical profile (from where most cases come) results revealed that although a number of 6 children were antenatally detected with renal diseases in the last decade, when the ultrasound technique and hospital equipment made more accessible positive diagnosis, neither of the fetus' undergoing surgery "*in uterus*" (Table I).

TABLE I
Detected diseases

	Antenatal	**Postnatal**
Number of patients	6	19
Percentage (%)	24	76

Correlating the results with recent literature data (15) we can assert that in the majority of the cases the diagnosis is set after the newborn age, most frequently at infant age when surgical intervention is performed, but positive diagnosis is set more easily in small children (1-3 years) when diagnosing methods are more permissive.

Four of the studied cases appeared in the neonatal period (between 10 days-1 month), at infant age, when they underwent surgical intervention in 9 of the cases, the other children (10 in number) were diagnosed between 1-3 year old and older, they also received surgical treatment, cystostomy, valve ablation etc. (2 children have not been operated yet) (Table II).

TABLE II
Moment of the surgical intervention

Age	Number of patients	%
0 – 12 months	4	17.39
0 -1 years	9	39.13
1 – 3 years	10	43.48

If in literature, the debut at infant age is quoted with a 30-36% frequency, between 1-5 year old with a 50-55% frequency, from the investigated casuistry apparently the number of diagnosed and operated cases appear at the infant age and it is increasing (13 infants).

At most of the infants were performed endoscopic valves ablations, a smaller initial number of cystomy, followed then in time II by valves resection. Their postoperative evolution was favorable. A child needed vesicostomy and a transpubian valve resection. No children of the studied group needed nefrostomy.

Although 3 children developed over time chronic renal failure, requiring peritoneal dialysis, none of them had to undergo a kidney transplant.

Nine children out of the studied group presented VUR, out of which being 5 bilateral. Regarding these results there is a similarity with the studied reference data. Other 4 children presented left or right vesicoureteral reflux of different types (Fig. 1).

In all 9 cases the treatment was performed surgically, from the ablation valves to cutaneous bilateral ureterostomies, vesicostomy and other subsequent corrections, the majority evolving propitiously with repeated urinal infections, although the diagnosis of posterior urethra valves in time still remain questionable.

This congenital malformation culminates in its evolution with renal failure (16) observed facts in cases 3, 4, 10, where the installation of uni- or bilateral VUR and repeated urinal infections relatively aggravated the evolution of the disease.

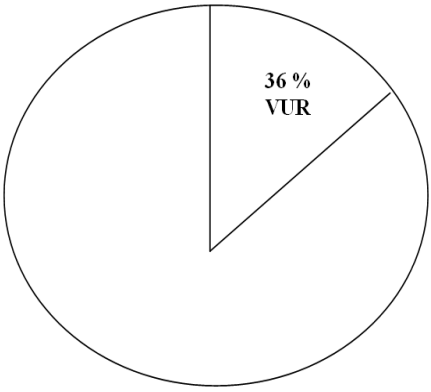

Fig. 1. Percentage of children discovered with VUR from the total number of children diagnosed with PUV

VUR may be considered as an associated gravity factor, 3 children required peritoneal dialysis and in the future probably undergoing renal transplant (17).

PUV are rare malformations of the posterior urethra, but their existence can lead to serious changes in the upper urinary system, culminating with chronic renal failure, despite the early surgical solution of the obstructed urethral, thus lowering the quality of life for children suffering from this diseases.

CONCLUSIONS

The majority of the studied cases presented favorable evolution and chronic renal failure in three cases, requiring dialysis and finally these patients possible undergoing renal transplant.

Vesicoureteral reflux, which can be secondary to the barrier, is interpreted as a

severe associated factor.

The diagnosis of PUV represents a challenge in the sense of detecting the impairment as early as possible and choosing the right therapeutic procedure in accordance with the degree of the renal impairment. Also it may be adversely influenced by: urinary infection, hypertension, bladder noncompliance. The diagnosis is more favorable when the reflux is unilateral, the heterolateral kidney being protected.

CONSIDERAȚII ASUPRA ETIOLOGIEI SINDROMULUI DISFAGIC LA PACIENȚII LARINGECTOMIZAȚI

Ana-Maria Corugă[1], V.N. Costinescu[2], Gina Stegaru[2]
1. Doctorand al Universității de Medicină şi Farmacie ,,Gr. T. Popa" Iaşi
Spitalul Clinic Județean de Urgențe ,,Sf. Spiridon"
2. Clinica Otorinolaringologie

ETIOLOGYCAL CONSIDERATIONS OF POSTLARYNGECTOMY DYSPHAGIA (Abstract): Dysphagia following laryngeal surgery is a common and severe symptom. Two life-threatening complications can compromise the patiens quality of life: pneumonia and malnutrition. Diagnostic procedures of swallowing disorders are represented by videofluoroscopic evaluation, CT scan and fiberoptics endoscopy. Material and methods: A retrospective evaluation was performed in a sample of 261 patients undergoing laryngectomy, hospitalized in the E.N.T Clinic of ,,St. Spiridon" Hospital, between 2006 and 2010. Postlaryngectomy dysphagia was diagnosed in 74 patients and was predominant in males (97,3%) aged between 50 and 60 years (37,8%). Results: Main causes of dysphagia were pharingocutaneous fistulas, tumor recurrences, postoperative cervical infections and hipopharyngeal stenosis. Conclusions: This study reveled the predominance of dyphagia in rural male patients undergoing total laryngectomy. Gastroesophageal reflux can represents a favoring factor of this type of dysphagia. **Key words**: DYSPHAGIA, LARYNGECTOMY, POSTOPERATIVE ANATOMICAL AND FUNCTIONAL CHANGES

Laringele are două roluri majore în cadrul procesului de deglutiție: asigură protecția căilor respiratorii (prin închiderea valvei trietajate alcătuită din epiglotă, benzile ventriculare şi corzile vocale) şi facilitează deschiderea sfincterului crico-faringian pentru trecerea bolului alimentar (prin ascensiune şi deplasare anterioară) (1). Dată fiind contribuția laringelui la buna desfăşurare a deglutiției, disfagia este un simptom comun rezultat în urma chirurgiei laringiene (2), disfuncțiile fiind mai severe şi frecvente, în comparație cu cele rezultate în urma extirpării tumorilor maligne cu alte localizări cervicale (1).

Disfagia se datorează în principal modificărilor anatomice şi funcționale apărute în urma extirpării totale sau parțiale a laringelui şi a reconstrucției faringelui, hipofaringele, esofagul superior şi laringele restant putând fi afectate major (1,3).

Cauzele disfagiei diferă în funcție de tipul de laringectomie.

În cazul laringectomiei totale, disfagia se poate datora spasmului muşchilor constrictori faringieni, spasmului şi deschiderii întârziate a sfincterului esofagian superior, stenozelor şi pseudodiverticulilor hipofaringieni, limitări mişcărilor bazei limbii, fistulelor faringo-cutanate, cât şi unor deficite ale nervilor cranieni. La acestea se pot adăuga lipsa coordonării musculaturii faringo-esofagiene la trecerea bolului alimentar şi îngroşarea sau proeminența peretelui

posterior faringian. (1,2,3,4,5). Frecvența disfagiei postlaringectomie este de 17-70% (2) sau 10-58% (4) din cazuri.

În laringectomiile verticale şi cele fronto-laterale, disfagia este severă şi greu tratabilă, putând avea drept cauză aspirația traheală, presiunea crescută din tractul faringo-esofagian, ascensiunea redusă a laringelui restant în timpul deglutiției şi incoordonarea mușchilor constrictori faringieni cu mușchiul crico-faringian (1,2,4,6).

Laringectomiile supraglotice produc disfagie mai frecvent decât laringectomiile totale (7).

Cordectomia produce disfagie minoră şi tranzitorie (1).

O complicație redutabilă şi frecventă a laringectomiilor, constant generatoare de disfagie, este fistula faringo-cutanată. Aceasta afectează 13% din pacienții laringectomizați (8). Studiile recente corelează apariția fistulei cu extensia tumorală la nivelul versantului laringian al sinusului piriform, impregnația tumorală a faringelui şi infecțiile locale postoperatorii (8,9).

Diagnosticul sindromului disfagic postlaringectomie necesită investigații diagnostice complexe: scintigrafia, videofluoroscopia, computertomografia, fibroendoscopia, microlaringoscopia, etc (1,4,5,10).

Tratamentul disfagie post-laringectomie este multimodal şi constă în tratament dietetic şi foniatric (1), medical şi chirurgical, fiind particularizat în funcție de cauza disfagiei. Stenoze hipofaringiene pot beneficia de dilatații sau faringoplastii (2,11). Fistulele faringo-cutanate pot fi închise prin sutură, faringoplastie cu grefe cutanate libere vascularizate (12) sau lambouri cutanate şi musculo-cutanate (13).

MATERIAL ŞI METODĂ

Studiul a avut drept scop identificarea cauzelor disfagiei la pacienții cu neoplasm laringian, internați şi operați în Clinica O.R.L a Spitalului „Sfântul Spiridon” din Iaşi în perioada 2006-2010.

Studiul a fost efectuat retrospectiv pe un eşantion reprezentativ statistic de 261 de pacienți cu neoplasm laringian operat.

Metodele de culegere şi interpretare a datelor au fost matematice şi statistice, realizându-se cu ajutorul unor echipamente şi programe informatice adecvate.

REZULTATE ŞI DISCUȚII

Lotul de studiu a fost alcătuit din 261 de pacienți cu neoplasm laringian operat : 13 femei (4,98%) şi 248 de bărbați (95,02%), 114 pacienți fiind din mediul urban (43,68%) iar 147 din mediul rural (56,32%).

În ce privește tipul de laringectomie:

168 de pacienți au suferit laringectomii totale (64,37%); 1 laringectomie totală cu faringectomie parțială (0,38%); 85 cordectomii prin tirotomie mediană (32,57%); 7 diverse tipuri de laringectomii parțiale: hemilaringectomie verticală, epiglotectomie, laringectomie frontală anterioară cu cordectomie lărgită bilaterală, laringectomie parțială bicordocomisurală (2,69%).

Distribuția cazurilor pe grupe de vârstă a fost următoarea: 4 pacienți au avut vârste cuprinse între 30 şi 40 de ani (1,53%); 36 pacienți între 40 şi 50 de ani (13,79%); 109 pacienți între 50 şi 60 de ani (41,76%); 72 pacienți între 60 şi 70 de ani (25,59%); 34 pacienți între 70 şi 80 de ani (13,03%) şi 6 pacienți între 80 şi 90 de ani (2,3%).

Preponderența neoplasmului laringian corespunde cu datele din literatură, aceasta fiind observată la sexul masculin (95,02%) şi la vârste cuprinse între 50 şi 70 de ani (67,35%).

Prin studiul lotului descris s-au identificat 74 de pacienți cu sindrom disfagic (28,35%): 72 de bărbați (97,3%) şi 2 femei (2,7%), 28 provenind din mediul urban (37,83%) şi 46 din mediul rural (62,17%).

Se observă preponderența sindromului disfagic la sexul masculin, corespondentă cu cea a neoplasmului laringian şi la pacienții din mediul rural, acesta putându-se datora adresabilității şi accesibilității mai reduse la serviciile medicale, condițiilor de igienă precare şi de educației sanitare deficitare.

Vârsta pacienților cu sindrom disfagic postlaringectomie a fost următoarea: 2 pacienți au avut vârste cuprinse între 30 şi 40 de ani (2,70%); 13 pacienți între 40 şi 50 de ani (17,56%); 28 pacienți între 50 şi 60 de ani (37,83%); 18 pacienți între 60 şi 70 de ani (24,32%); 12 pacienți între 70 şi 80 de ani (16,21%) şi 1 pacient între 80 şi 90 de ani (1,35%), comparabilă cu distribuția pe vârste a lotului studiat. Se observă preponderența netă a disfagiei datorată laringectomiilor la grupa de vârstă 50-60 de ani.

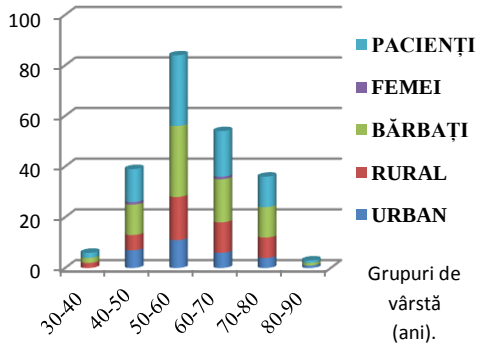

Fig. 1. Distribuția pacienților disfagici în funcție de vârstă, sex, mediu de domiciliu.

Extensia tumorală locală a fost T1-T2 la 20 de pacienți (27%) şi T3-T4 la 54 de pacienți (73%), reprezentând factorul principal în stabilirea tipului de intervenție chirurgicală. Astfel, au fost efectuate laringectomii totale la 52 de pacienți (70,3%), cordectomii la 18 pacienți (24,32%) şi alte tipuri de laringectomii parțiale la 4 pacienți (5,4%).

Studiind cauzele disfagiei în funcție de tipul de laringectomie au rezultat următoarele date :

În cazul celor 52 de pacienți cu laringectomii totale, cauzele sindromului disfagic au fost: fistulele faringo-cutanate la 23 de pacienți, recidivele tumorale sau continuările evoluției tumorale la 8 pacienți, supurațiile cervicale anterioare de etiologii diverse (serom cervical suprainfectat, granulom de fir abcedat) la 8 pacienți, dehiscența plăgii operatorii la 2 pacienți, fistula traheo-esofagiană la 1 pacient şi stenoza hipofaringiană la 2 pacienți. La 7 pacienți, sindromul disfagic a avut cauze multiple, combinate (fistulele faringo-cutanate, recidivele tumorale sau continuări de evoluției tumorale, supurațiile cervicale anterioare).

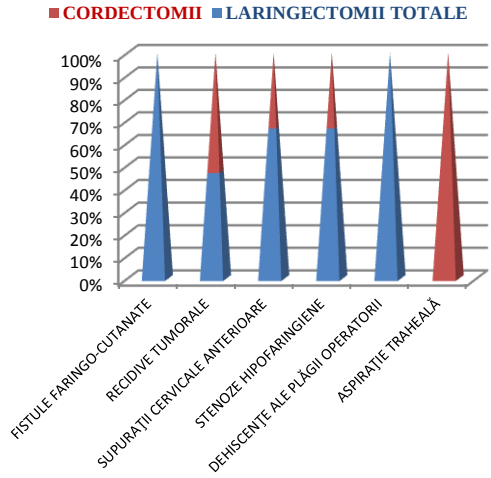

Fig. 2. Tipuri de laringectomii efectuate la pacienții disfagici.

Cordectomiile prin tirotomie mediană au fost urmate de sindrom disfagic datorat în special recidivelor tumorale sau continuărilor evoluției tumorale în 9 cazuri, supurațiilor cervicale anterioare în 4 cazuri, dehiscenței plăgii operatorii într-un caz, stenozei hipofaringiene într-un caz şi fără cauză aparentă/aspirație traheală în 3 cazuri.

Celelalte tipuri de laringectomii parțiale au fost urmate de recidive sau continuări ale evoluției tumorale ce au necesitat totalizarea laringectomiei. Au fost urmate de fistulele faringo-cutanate recidivante şi ulterior de stenoze hipofaringiene.

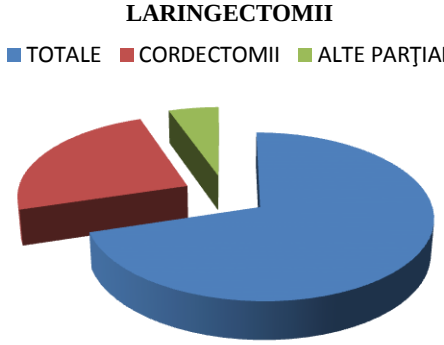

Fig. 3. Cauzele disfagiei în funcție de tipul laringectomiei.

Diagnosticul cauzal al sindromului disfagic la pacienții laringectomizați a fost stabilit prin examinare clinică şi explorări paraclinice, în special computertomografie cu substanță de contrast şi endoscopie.

Tratamentul a fost complex, fiind orientat în funcție de cauza disfagiei. În cazul fistulelor faringo-cutanate şi dehiscențelor plăgii operatorii s-a practicat sutura simplă per secundam sau faringoplastia cu lambouri cutanate şi musculo-cutanate cât şi cu grefe libere, intervenții susținute de alimentație parenterală şi vitaminoterapie. Pentru recidive şi continuări ale evoluției tumorale s-a practicat totalizarea laringectomiei, urmată de radio şi chimioterapie. Supurațiile cervicale au necesitat incizie şi drenaj asociate cu antibioterapie.

CONCLUZII

Studiul realizat pe un lot de 261 de pacienți cu neoplasm laringian operat în ultimii 6 ani, relevă predominența sindromului disfagic rezultat în urma laringectomiei la pacienții de sex masculin: (97,3%) proveniți din mediul rural; (62,17%) cu vârste cuprinse între 50 şi 80 de ani (79,7%).

Disfagia apare mai frecvent în urma laringectomiilor totale (70,27%), primele două cauze fiind reprezentate de fistulele faringo-cutanate şi recidivele sau continuările de evoluție tumorală. Între aceste două cauze a fost stabilită o corelație, fistulele faringo-cutanate fiind frecvente în cazul ablației incomplete a tumorii, urmată firesc de recidivă.

Alte cauze posibil generatoare de fistule faringo-cutanate şi implicit disfagie ar putea fi refluxul gastro-esofagian, hipersalivația şi deglutiția frecventă.

Cantonarea microbiană în special cu pseudomonas şi candida, generatoare de aciditate se pare că ar favoriza apariția fistulei faringo-cutanate.

Pentru a preveni apariția fistulelor faringo-cutanate, în Clinica O.R.L. a Spitalului „Sf. Spiridon", pacienții laringectomizați sunt monitorizați atent în vederea depistării precoce a acestor factori favorizanți.

Tratamentul preventiv constă în administrarea inhibitorilor pompei de protoni (omeprazol, pantoprazol, esomeprazol) în cazul refluxului gastro-esofagian, a antibioticelor şi antimicoticelor, în conformitate cu antibiograma sau antifungigrama în cazul infecțiilor şi a anticolinergicelor (atropina) pentru a reduce secreția salivară.

THE IMPACT OF RENAL DENERVATION ON THE BAROREFLEX CONTROL OF HEART RATE IN AN EXPERIMENTAL MODEL OF REDUCED RENAL MASS, SALT SENSITIVE VOLUME-OVERLOAD HYPERTENSION (Abstract): **Background**. Beyond lowering arterial blood pressure in hypertensive patients, renal denervation (RDNx) has also been shown to improve the cardiac autonomic nervous system, particularly in sympathetically mediated cardiovascular disorders. Nevertheless, little is known about the efficiency of renal nerve ablation in non-mediated sympathetically diseases. Therefore, our aim was to investigate the influence of renal denervation on the cardiac autonomic nervous system in an experimental rat model of salt sensitive, volume-overload hypertension developed after surgical reduction of renal mass (RRM) by 75-80% and salt loading. **Material and methods:** The dynamic time-dependent cardiac autonomic system analyses such as the baroreflex sensitivity (BRS), the power of the fluctuations of the heart rate in high frequency range (0.75-3Hz, HF power) and both short and long-term beat-to-beat variability were calculated from continuously recorded cardiac cycles before and after surgical RRM by 80%, including here RDNx and central sympathoinhibition with clonidine. **Results:** The BRS decreased significantly throughout the entire 2 weeks of the development of salt-sensitive, volume overload hypertension induced after surgical RRM and high salt diet. After RDNx, the HF power decreased during the first 7 days, paralleling the alterations of both long and short-term heart rate variability. Global sympathoinhibition after clonidine administration significantly improved the cardiac autonomic nervous system as reflected by the substantial enhancement of the BRS, the HF power and both short and long-term heart rate variability. **Conclusions:** The present results indicate that in salt-sensitive, volume overload hypertension, the cardiac autonomic nervous system is impaired, and these alterations are not improved over the long term by RDNx. On contrary, central sympathoinhibition after clonidine administration following RDNx significantly improved BRS, the HF power and both short- and long-term beat-to-beat variability. **Keywords**: HYPERTENSION, RENAL DENERVATION, CARDIAC AUTONOMIC NERVOUS SYSTEM, BAROREFLEX, HEART RATE VARIABILITY.

The arterial baroreflex plays a crucial role in maintaining the homeostasis of the cardiovascular system by reflexively modulating the balance between sympathetic and parasympathetic activity (1-3). Baroreflex dysfunction has been associated to many cardiovascular diseases that lead to autonomic imbalance and thus likely contribute to the progression of disease. Impairment of the baroreflex control of the heart rate has been found in patients with heart failure, myocardial infarction, coronary artery disease and essential hypertension (2, 4-7). While baroreflex dysfunction *per se* is correlated with a high mortality risk (8-10), reductions in heart rate variability (HRV), likely due to impaired baroreflex control of the cardiac autonomic outflow, has also been recognized as a predictor and a risk factor for developing life-threating atrial and ventricular tachyarrhythmia (11-16). Furthermore, since dysfunction of the baroreflex system has also been described in patients with treatment resistant hypertension (RHT) (17) these patients are likely exposed to arrhythmic risk (18).

Recent clinical and experimental studies indicate that ablation of the renal nerves may improve both baroreflex sensitivity (BRS) and HRV in patients with RHT (19, 20). Importantly, these effects occur in parallel to the lowering of blood pressure, thus indicating a putative beneficial cardioprotective effect. Overactivation of sympathetic efferent renal nerves increases blood pressure by stimulating renin secretion and renal tubular sodium reabsorption and interruption of these pathways by renal denervation (RDNx) is considered to underlie most of the antihypertensive effects of this non-pharmacological approach (21). However, RDNx also interrupts sympathoexcitatory afferent signaling from the kidneys, which may contribute to global sympathoinhibition, in addition to the renal-specific effects. An improvement in the baroreflex control of sympathetic outflow or suppression of the central sympathetic outflow via hypothalamic pathways has been suggested to mediate these latter effects (22, 23). Although the lowering of blood pressure and the improvement of autonomic function following RDNx appear to be efficient in conditions associated with sympathetic overactivation, it remains unclear whether these beneficial effects are also manifest in the absence of an increased sympathetic outflow.

The remnant kidney model is mainly used to investigate the pathophysiology of the RHT related to non-ischemic nephron loss and has the major advantage to closely replicate many of the abnormalities of this clinical condition (24). In this model of salt-sensitive, volume overload hypertension following surgical reduction of 75-80% of the renal mass, we have previously shown that the global sympathetic nervous system activity is actually reduced and RDNx does not further lower sympathetic activity, thus lacking sustained antihypertensive effects (25). However, it is unclear whether baroreflex function and HRV are altered during the development of salt-sensitive hypertension and whether RDNx may have beneficial effects on the baroreflex control of heart rate in the absence of a sustained antihypertensive and global sympatholytic effect. Considering the recent observations regarding the anti-arrhythmic effects in patients undergoing RDNx (19, 26-29), we hypothesized that renal nerve ablation may improve cardiac BRS and HRV in this clinically relevant model of human RHT. This evaluation in this experimental model which shares many of char-

acteristics of RHT may be important clinically because many patients with RHT are at high risk for detrimental cardiac arrhythmias (17, 18).

To test this hypothesis, spontaneous oscillations of blood pressure and heart rate were continuously analyzed in the time and frequency domains, to determine the daily time course of cardiovascular dynamics under different salt-loading conditions during normal renal function and throughout the progression of salt-sensitive hypertension following reductions in renal function. Furthermore, the ability of the renal denervation to improve cardiac baroreflex, and ultimately the HRV was evaluated. Finally, the response of the cardiovascular dynamics to global suppression of sympathetic outflow with clonidine was assessed.

MATERIAL AND METHODS

All experiments were performed according to the European Directive 2010/63/EU on the Protection of Animals Used for Scientific Purposes and were approved by the Research Ethics Committee of the "Grigore T. Popa" University of Medicine and Pharmacy Iași. As previously describe (25), eight adult male Sprague Dawley rats (28-32 weeks of age) were used in this study. The animals were obtained from the National Research Institute "*Cantacuzino*" (Bucharest, Romania). Rats were housed in a temperature (21-23°C) and humidity-controlled environment with a 12 hours light/dark cycle, with *ad libitum* access to food and water. Animals were fed a standard rodent diet containing either 0.8 % NaCl (Normal salt, NS), 0.1 % NaCl (Low Salt, LS) or 4 % NaCl (High Salt, HS) (National Research Institute "Cantacuzino" Bucharest, Romania). The long-term cardiovascular responses (24 hours averages) data from this study have been presented in a previous publication (25). The present study was designed to investigate the detailed time-dependent dynamic changes of baroreflex control of heart rate, as well as HRV.

Animal preparation

All surgical procedures aimed for continuous acquisition of blood pressure, surgical reduction of renal mass and renal denervation of the remnant kidney have been previously described (25).

Data acquisition and analysis

Arterial blood pressure was continuously recorded using implantable radio telemetry system. For signal acquisition and wireless charging of the implanted telemeters rats were placed on TR181 smart pads (*Millar, Inc., Houston, TX*)(25). The individual 24-h BP waveforms were acquired continuously at a sampling frequency of 2000 Hz using a PowerLab 16/35 data acquisition system (*ADInstruments, New South Wales, Australia*). All individual cardiac cycles were recorded continuously (on every day between 7.00 AM to 6.00 AM recordings, excluding the one hour necessary for daily animal care). The dynamic time-dependent cardiac autonomic system analyses were performed under both normal and reduced renal mass conditions, with the associated phases of the developing and established volume-overload hypertension, including here the renal denervation and the central sympathoinhibition with clonidine (in doses of 300 and 150 μg/kg/day in the drinking water with daily adjustment of the concentration per fluid intake to attain desired drug intakes). For subsequent time- and frequency-domain analyses, daily time series of beat-to-beat

systolic blood pressure (SBP) and pulse intervals (PI) were generated from artifact-free 23 hours long blood pressure waveforms with LabChart Pro v8.1.8 (*ADInstruments, New South Wales, Australia*) and peak detection algorithms.

Estimation of baroreflex control of heart rate

BRS was computed using frequency domain analyses as previously described. Briefly, a spectral analysis of the daily beat-to-beat data based on the Fast Fourier Transformation (FFT) was performed using MATLAB routines (*R14; MathWorks, Natick, MA*) using algorithms we have previously described (16, 30). The BRS was estimated as the magnitude of the transfer function between SBP and PI within 0.05 - 0.5 Hz frequency range.

Heart rate variability measurements

HRV measurements were performed using both time and frequency domain analyses. Long-term heart rate variability was obtained from time domain analyses entailing in determination of the standard deviation (SD) of all pulse intervals during a 23-hours. period. Short-term variability was computed as the means of the standard deviation calculated for all 5-min segments for the entire 23 hours period (SDNN) (31). The power of the heart rate oscillations within 0.75-3 Hz band (HF power) from the daily R-R interval variations, reflecting the parasympathetic control of the heart rate, was computed using the non-parametric lomb periodogram algorithm implemented into LabChart module (*LabChart Pro v8.1.8*).

Experimental design

Normal renal function and associated salt resistant hypertension

1. After implantation of the telemeters, the rats were allowed to recover for 2 weeks until the circadian rhythmicity was fully restored. Cardiac autonomic nervous system responses from control period were recorded while the animals were fed with normal salt (NS) diet. To assess the cardiac autonomic nervous system regulation during normal renal function and associated salt resistant hypertension, the salt intake varied as follows: for 7 days the rats were fed with LS, followed by another 7 days of HS diet. At the end of the second week, the LS diet was initiated and maintained until the mean arterial blood pressure and heart rate values plateaued around the levels from control period.

Reduced renal mass and associated salt sensitive hypertension

Cardiac autonomic nervous system responses were assessed continuously throughout the entire experimental periods as described below. Surgical RRM was performed as previously (25). Following the post-surgical recovery period, the HS diet was initiated and maintained for the next 6 weeks. After two weeks of HS diet, when arterial blood pressure significantly increased and plateaued at hypertensive levels, RDNx of the remnant left kidney was performed as previously described (25). Two weeks after RDNx, the cardiac autonomic nervous system responses to centrally sympatholytic clonidine were assessed. Finally, in the last week of the experiment, the rats were subjected again on LS diet.

Statistical analysis

Results are expressed as Mean ± SE. One-way, repeated measures ANOVA followed by Dunnett's multiple comparison test were used (*Prism 6.01, GraphPad Software*) to compare the experimental

periods mentioned here below and the differences were considered statistically significant for $p<0.05$.

Normal renal function

→ daily cardiac autonomic nervous system regulation during:

1) LS (days 5-11; 19-21) to NS control period (days 2-3);

2) HS (days 12-18) to NS control period (days 2-3);

Reduced renal mass and associated salt sensitive hypertension

→ daily cardiac autonomic nervous system regulation during:

1) HS (days 40-53) to LS (days 38-39);

2) HS + RDNx (days 54-67) to HS (days 52-53);

3) HS + RDNx + clonidine 300 μg/kg/day (days 68-73); + clonidine 150 μg/kg/day (days 74-76); + clonidine washout (days 77-81) to HS + RDNx (days 66-67);

4) LS (days 82-87) to HS + RDNx (days 80-81).

RESULTS

Responses during normal renal function and associated salt resistant hypertension.

As shown in the figure 1A, the estimated BRS as the magnitude of the transfer function between systolic blood pressure and pulse interval did not change during both LS and HS. While the HF power (fig. 1B) increased in the last day of the LS, it decreased significantly throughout the entire HS period. Although long term beat-to-beat variability did not suffer any alterations (fig. 2A), short term beat-to-beat variability decreases during both LS and HS periods (fig. 2B), paralleling the HF power.

Figure 1

Baroreflex sensitivity (**Panel A**) and the power of the fluctuations of the heart rate in high frequency range - HF power - **(Panel B)** responses to varying salt intake during normal renal function. Values are men ± SEM. Normal renal function: * $p < 0.05$ vs. NS Control (days 2-3). Respective baseline days are depicted as (○).

Figure 2

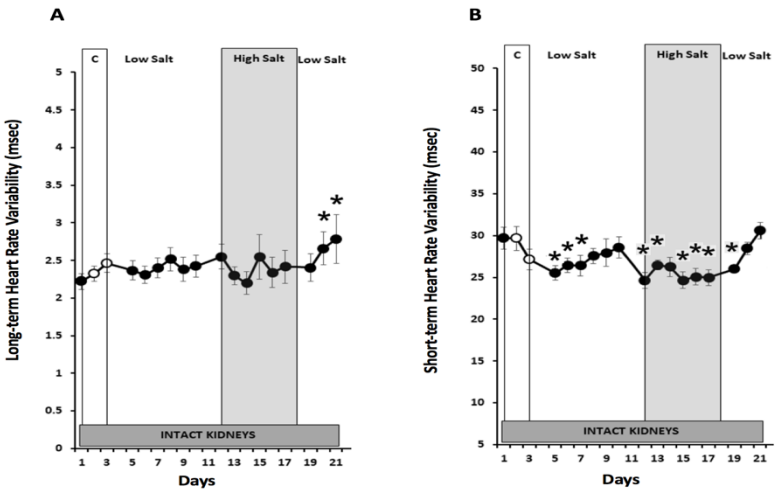

Fig. 2. Long (**Panel A**) and short-term (**Panel B**) beat-to-beat heart rate variability responses to varying salt intake during normal renal function. Values are men ± SEM. *Normal renal function*: * $p < 0.05$ vs. NS Control (days 2-3). Respective baseline days are depicted as (○).

Responses to renal denervation during established salt-sensitive, volume overload hypertension

Compared to the last 2 days of previous period of HS loading, the estimated BRS slightly increased at the end of the 2 weeks after renal denervation (fig. 3). As shown in figure 4, the HF power decreased during the first week after renal denervation, paralleling the alterations of the long- and short-term beat-to-beat variability (fig.5 and fig. 6). These changes induced by renal denervation were only transient, as all variables gradually returned towards pre-denervation levels within a week and were stable subsequently, except estimated baroreflex sensitivity which remained at higher levels than control period.

Responses to central sympathoinhibition during established salt-sensitive, volume overload hypertension

As depicted in figure 3, global sympathoinhibition induced by clonidine administration in doses of 300μg/ kg significantly increased the BRS. Moreover, the HF power significantly increased (fig. 4) and all these changes were accompanied by a marked increase of both long- and short-term beat-to-beat variability (fig. 5 and fig. 6). Then, during the clonidine dose tapering (150 μg/ kg) and the following washout period, all the variables gradually returned to post-denervation values.

Responses to salt restriction after reduced renal mass

No further changes of the BRS occurred along the last week of the experiment when the animals were on LS diet. The HF power slightly increased at the end of the last week (fig. 4), accompanied by the same variation of the short-term heart rate variability (fig. 6).

DISCUSSION

A significant reduction of the estimated BRS during the development of salt-sensitive, volume overload hypertension following non-ischemic reduction of the renal mass and HS diet was found in this experimental study. Our results are in line with previously published data from experimental and clinical studies that show a blunted baroreflex sensitivity in both non-ischemic (32) and ischemic renovascular hypertension (33, 34). Although in the ischemic forms of the renovascular hypertension the impairment of the BRS is associated with the activation of the sympathetic nervous system (34, 35), little is known about the mechanisms responsible for the cardiac autonomic nervous system dysregulation in the non-ischemic renovascular arterial hypertension. While BRS decreased during high salt diet and associated progression to salt-sensitive, volume overload hypertension, both long and short-term heart rate variability did not paralleled the baroreflex evolution, possible due to involvement of the low-pressure cardiopulmonary mechanoreceptors in the heart rate control triggered by fluid overload (36). Moreover, we also found that the estimated BRS tended to be decreased during salt loading with normal kidney function although this effect did not reach statistical significance. During this time, both time- and frequency domain measures of heart rate variability were lower, as compared to normal salt intake. These findings are consistent with clinical (37) and experimental studies (38, 39) indicating that the sensitivity of the baroreflex control of heart rate is depressed during high salt diet in normotensives as a consequence to reduced sensitivity of the mechanoreceptors, possibly due to local alterations in the ionic milieu in the carotid sinus region (40-42). Tonic increases in central sympathetic outflow may also be responsible for the reduced variability of heart rate during exposure to high salt levels. Indeed, we have previously shown that during salt loading on normal kidney function, the sympathetic activity estimated from the power of the blood pressure oscillations in the low frequency range was increased (25). Furthermore, in normotensive rats, the magnitude of the sympathetic nervous system activation is directly correlated with the level of dietary sodium intake because of a NaCl-induced sensitization of the central autonomic pathways (43), likely involving neurons within rostral ventrolateral medulla (44-46). Although the activation of the sympathetic nervous system mediated through central mechanisms in response to salt loading could underlie the impairment of the cardiac autonomic modulation during salt-resistant hypertension, other mechanisms are likely responsible for the impairment of the BRS during salt-sensitive hypertension since the global sympathetic activity is actually decreased as we have previously described (25).

Recent experimental and clinical investigations suggest that beyond antihypertensive effects, renal denervation is also effective in reducing the incidence of arrhythmias particularly in cardiovascular diseases associating high levels of sympathetic activation such as chronic heart failure (47-51). In contrast, in this model of salt sensitive hypertension, in the absence of overt sympathoexcitation, we found that renal denervation did not improve baroreflex sensitivity, cardiac parasympathetic tone or short- and long-term heart rate variability. Furthermore, during the first week after renal nerve ablation these parameters decreased significantly and returned to pre-denervation levels only during the second week after denervation. Together with our previous findings indicating the lack of

sustained antihypertensive effects of renal denervation (25), our current data suggest that the failure of renal denervation to lower global sympathetic activity in this model of salt sensitive hypertension and non-ischemic reduction of renal function may also be responsible for its inability to improve the cardiac autonomic regulation.

The above contention is further supported by the responses to central sympathoinhibition with clonidine. In parallel with lowering sympathetic activity (25), Clonidine also significantly improved the sensitivity of the baroreflex system, the parasympathetic tone to the heart and both short and long term beat-to-beat heart rate variability. The improvement of the baroreflex sensitivity reported in our study is in line with the other results showing that by exerting a direct effect on baroreceptors themselves (52) or by stimulating the alpha-2 adrenoceptors from the *vagus nuclei* (53), clonidine is able to increase the cardiac parasympathetic tone and therefore the baroreflex sensitivity and heart rate variability.

CONCLUSIONS

The major findings of this study are: 1) during salt-sensitive, volume overload hypertension developed after non-ischemic reduction of renal mass, the BRS is reduced, 2) in this phenotype of non-sympathetically mediated arterial hypertension RDNx does not improve over the long term the BRS and 3) central sympathoinhibition after clonidine administration following RDNx led to a significant improvement of the BRS, parasympathetic modulation of the heart rate and both short and long term HRV.

GIANT LIPOMATOUS TUMORS OF THE UPPER EXTREMITIES – A SERIES OF 8 CONSECUTIVE CASES (Abstract): We present a series of eight consecutive patients evaluated in our department from 2002 to 2007 with giant lipomatous tumors (as defined in medical studies as greater than 5 cm) of upper extremities. There were three male and five female, ranged in age from 17 to 77 years (mean age of 55). The tumor's size ranged from 5 to 34 cm. All patients underwent total excision of the tumors with free margins. All specimens were sent to pathology: seven patients had benign tumors and one patient had liposarcoma. There were no recurrences of the tumors. Appropriate preoperative evaluation and complete surgical excision are mandatory for successful treatment of these tumors. **Key words**: GIANT LIPOMA, LIPOMATOUS TUMORS, UPPER EXTREMITY
